tioned before in connection with its frequency
Egypt, although it is also found in other parts
Africa, Arabia, and Iraq. There are two ma
types: one infecting the bladder (*schistosom*
haematobium), the other the rectum (*schistosom*
mansoni). Bilharzia is more correctly known
schistosomiasis.

The parasite's fantastic life-history beg
when a man bathes in infected water, and
small swimming forms known as cercariæ pie
and enter his skin—or they may enter the bo
by drinking infected water. From the skin th
pass to the portal vein below the liver, rema
there six weeks until they become adult and th
swim against the blood-stream down to
pelvis, where the female lays eggs which hav
sharp spine. The eggs penetrate into the blad
or rectum—depending on the type of fluke—a
pass out in the fæces or urine. If they en
water they hatch out into small moving for
which seek out a water-snail, develop further
its body, and leave it in the form of cercariæ rea
to find a new human victim. The female flu
is slender and round, about 1 in. in length,
male, flat and leaf-shaped, is about $\frac{3}{4}$ in. long, a
as we have seen, their grisly courting takes pla
in the portal vein, whence the impregnated fem
passes to the bladder (hæmatobium) or rect
(mansoni) to lay her eggs.

Infection results in raised temperature and, in e urinary type, blood in the urine; in the estinal type blood is found in the fæces, and ere are symptoms resembling dysentery— ., diarrhœa. Treatment in both cases is by ections of antimony tartrate. Needless to say, empts should be made at prevention by telling ople to avoid infected canals (usually easier d than done), and by periodically cutting off e water supply to the canals to kill the snails.

Hookworm Disease, or ankylostomiasis, is found many parts of the world, especially in miners o work on damp ground. The tiny worm enters e body usually through the feet, passes through e blood-stream to the lungs, eats through into e of the bronchial tubes, climbs the windpipe, d passes down the œsophagus into the stomach end up in the duodenum. It causes anæmia, n be fairly readily cured, but is occasionally al.

Elephantiasis. Some types of parasitic worm spread by insects. Thus in *Filiarisis* mostoes inject by their bites the infantile forms a tiny worm which enters the lymphatic nnels; there the blockade they cause leads the swelling of the legs and the lower part of body, known as elephantiasis.

PHYSICAL INJURIES

INTRODUCTION.

n this section we shall inevitably discuss much t could be described as Principles of First . You cannot learn First Aid from a book, n if you read one of the excellent first aid nuals, like those published by the St. John bulance Association. The only way is to a one of their many classes of practical and oretical instruction which are held in all parts his country and many others. There is much be said for many more people receiving inction, to judge by the level of general ignorance ineffectiveness to be witnessed at most road idents before the ambulance comes.

he most difficult thing to learn is what *not* to When a patient is knocked down in the road, ple instinctively seem to want to drag him nediately to his feet, or otherwise pull him on he pavement away from the traffic. Someone have entered the nearest shop and be emerging a chair so that the casualty can sit down. ore long a hot strong sweet cup of tea has ved, and this or some other beverage is being red into him. All this is instinctive, and all t is wrong. Do *not* move the patient until are sure he has no fracture which will be her aggravated by movement. To take an eme case, a fractured spine clumsily moved result in permanent widespread paralysis. rd your patient from the traffic but only ve him when you are certain it is safe to do so. e has any injury which is likely to require a eral anaesthetic on arrival in hospital (and applies to most fractures) do not give anyg at all by mouth. No anaesthetic can be n to a patient who has eaten or drunk anyg in the previous three hours, in case he vomits e unconscious and dies of obstruction of his ay. Keep your patient warm (do *not* warm up artificially) keep his head low, and unless s bleeding severely or has stopped breathing, othing but protect him from the ministrations ne uninstructed until the ambulance comes.

ries to the Head and Back.

ne head contains the brain, an organ with a ber of inconvenient properties from the point iew of injury. Its very great importance is hed by its very great vulnerability as a tissue. consistency is that of stiff junket. It is e incapable of repair once damaged and cannot by growing new parts in the way that skin and bone can. So it has to be totally enclosed by protective bone which means it cannot swell without compressing itself dangerously within its box—and this not infrequently happens after injury. Furthermore, any bleeding into the interior of the skull can only occur at the expense of compressing the brain, since the brain box is already fully occupied by the brain. There is a story in first aid known as "Concussion and Compression." It begins with a knock-out blow to the head and this is known as concussion. The patient struck a hard enough blow to the head will lose consciousness, if only for a short time, due to the brain being shaken up. Even slight knocks would do this if the brain were not cushioned by a thin layer of cerebrospinal fluid. Most concussed patients quickly regain consciousness, and for the great majority that is the end of the affair except for a sore head and a headache for a few days. Unfortunately for a minority, even though there may have been no fracture, the blow that knocked them out will also have damaged a small blood vessel on the surface of the brain. These patients may be indistinguishable from the luckier ones at first. They may have regained consciousness and will be just as anxious to go home. They will often be quite lucid for some hours. Surgeons call this the "lucid interval." However, when more than a certain amount of blood has accumulated in the head, and the brain is sufficiently compressed by it the patient loses consciousness slowly, for a second time, and from this phase of "compression" he will not recover unless something is done. The lucid interval can last some hours. Brain surgeons can relieve the compression and save the life of the patient only if they have him in their care when it occurs. This is why *all* cases of head injury who have once lost consciousness (concussion), for however short a period of time, and however lucid they may subsequently appear, *all* must be seen by a doctor and, if thought necessary, observed overnight in hospital, in case they are bleeding and proceeding to compression. There is no way of saving these avoidable fatalities other than by treating all cases of concussion seriously. Fractured skull is potentially even more serious, because the blow will have been harder and, the brain is therefore more seriously at risk.

The spinal cord can be regarded as an extension of the brain which runs down the middle of the spinal bones of the vertebral column. It has the same delicate consistency, and the same inability to recover from injury as the brain. Injury is usually the result of a fracture-dislocation of the spine. The consequences of injury are due to a permanent interruption of its two main functions. All movements of the voluntary muscles are only possible if they are connected by nerves to the brain. Except for muscles in the head, all these "motor" nerves run in the spinal cord. The nerve pathways leave the skull through a large hole in its base and run down in the spinal cord to the required level. They then emerge between the spinal bones and travel in bundles to reach the muscles. Motor nerves for the arm leave the cord between the vertebrae of the neck. Those for the leg leave the cord in the lumbar region in the small of the back. If the nerve supply is damaged in any part of its course, the muscles being supplied become paralysed and are unable to move. It follows that if the spinal cord is damaged, all muscles below the point of damage have been cut off from the brain, and will be paralysed, and this will be permanent because the cord cannot be repaired. Damage to the nerve pathway *after* it has left the cord can often be repaired. Permanent paralysis is only one of the consequences of cord damage, since there is another whole series of nerves running in the cord which carry sensations from all parts of the body to the brain. Therefore there will be loss of sensation as well as paralysis below the point of injury.

It is emphasised that fracture of the spinal bones can occur without damage to the cord taking place. It is when these bones move one over the other, or "dislocate," that permanent cord damage occurs. It is therefore extremely important that cases of back injury be moved very carefully indeed in order to avoid such a disaster, and special ways of moving such patients are taught in First Aid classes.

Haemorrhage and Shock.

Every part of the body must have a blood supply, or else it will die. It is possible to stop the blood supply to a leg, for example, by fastening a wide rubber bandage tightly around the top of the thigh. This so-called " constrictive bandage " is still mentioned in First Aid books as a desperate means of controlling haemorrhage in a limb. It should hardly ever be used, because by stopping all circulation of blood, the entire limb will die in the course of time. Besides, most haemorrhage can be stemmed by direct pressure on the bleeding point. The tissues of the leg, such as its muscle and skin and bone will begin to die in a little more than half an hour after cutting off the blood supply. The brain, however, will begin to suffer within three *seconds* of its blood supply being cut off, and will die in about three minutes. Thus it can be seen that some parts of the body are more susceptible than others to a failure of the blood supply and the brain suffers earliest of all. Since the brain is where most of the vital functions of the body are controlled, it follows that a shortage of blood to the brain is likely to lead to a " depression of the vital functions "—a state of affairs known to First Aiders as "'shock."

Shock occurs in a number of conditions, but is always due to a failure of the supply of blood to the vital functions of the brain for one reason or another. Its usual causes are:

(1) haemorrhage, when there is a general shortage, but the brain feels it most;

(2) severe burns, in which much fluid is lost from the blood as will be seen later; and

(3) certain medical conditions causing acute heart failure in which there is a failure to pump blood to the brain because the pump has failed.

The treatment for shock consists basically of restoring the blood supply to the brain, and where it is caused by loss of blood or other fluid, the treatment is transfusion. Finally, it must be emphasised that treatment is always urgent, since the brain cannot function for long without its blood supply, and once damaged by the shortage, can never be repaired. No attempt is made here to describe such treatment completely, but the most important things are to keep the head low so as to reduce the work the heart must do to drive blood to the brain; and to avoid artificial heating of the body by hot water bottles, etc., which only diverts blood away from the brain where it is needed, into the skin where it is not.

The treatment of severe haemorrhage is to stop the bleeding, usually by firm, direct pressure, and then to remember above all things that even though the bleeding has stopped, there may be a dangerous state of shock from which the patient could die. This can only be prevented by restoring the circulation to the brain, usually by transfusion; so, having stopped the bleeding drive him fast to hospital for the second part of the treatment which may be as necessary to save his life as the first.

There is great confusion over the use of the word " shock." In the lay mind it is a shake-up of the nervous system caused by a fright, or some bad news, or the sight of something nasty in the woodshed. Even in the medical mind it is sometimes confused, and some of the First Aid books confuse it still further. Too frequently they give the treatment as " loosen all tight clothing from neck, chest, and waist; reassure the casualty and ensure a good supply of air." All this, together with grandmother's hot strong sweet tea is perfectly good enough if the patient is only " shaken-up " by a fright or a fall, but it will be dangerously negligent and time-wasting if he is suffering from true shock due to a failure of blood supply to the brain.

Fainting is a special case which can be prevented by keeping the head low in those who feel faint. It is usually self-curing due to the patient automatically falling into a position in which the head is low. If the faint, however, is due to severe blood loss, this is the same as shock in our proper meaning of the word and must be treated accordingly.

Haemorrhage can therefore be a difficult problem. It is even more so when it is internal. This may be in *medical* cases such as in occasional cases of peptic ulceration in which the blood will be vomited and also passed in the stool. Or it may be *surgical*, in the sense of being caused by injury to internal organs. The blood may emerge from one or other of the various orifices of the body, or it may be entirely concealed within the body. Rupture of internal abdominal organs such as the spleen, kidney and liver can occur with surprisingly little to show in the way of external injury. A fractured thigh bone can pierce the main artery of the leg and cause lethal internal haemorrhage without a drop of blood being visible. In all these cases diagnosis is urgent, followed by emergency blood transfusion if the brain, and hence the patient's life, is to be saved.

Means of detecting the presence of severe haemorrhage without seeing any blood are taught in First Aid Classes as the Signs of Haemorrhage. They are in fact manifestations of the reactions of the body in its attempts to save the failing brain, and are therefore the same as the signs of shock. The main ones are a rapid, feeble pulse, getting more rapid and more feeble as time goes on in a desperate attempt to get the remaining blood to the brain; skin pallor caused by constriction of blood vessels near the surface so that the blood which remains is shunted to the brain away from the less vulnerable skin; and finally, just before death, restlessness and air hunger.

A word of warning about the First Aid treatment of shock due to heart attack (coronary thrombosis). These patients must be transported at complete rest, but many of them react very badly to being made to lie down, since they have great difficulty in breathing in this position. Transport them relaxed, in a sitting position, supported by a large comfortable back rest.

It cannot be too strongly emphasised that with haemorrhage and shock, as with so many First Aid emergencies, the importance of protecting the brain is paramount.

Asphyxia.

The previous section was concerned with maintaining an adequate supply of blood to the brain. This is needed in order to supply the brain's only possible fuel—glucose—and the oxygen with which to burn it. Many different circumstances can conspire to reduce the oxygen content of the blood, and the result in each case is asphyxia. Normally, air is taken into the lungs through the air passages and brought into contact with all the circulating blood. It diffuses from the lungs into the blood, where it enters into a special relationship with the pigment of the red cells—haemoglobin. At the same time, the waste gas carbon dioxide enters the lungs from the blood and is breathed out. The revitalised blood is passed through the heart to build up sufficient pressure to drive it into all the tissues of the body, and in particular into the brain. A special system in the brain—the respiratory centre—controls the complicated machinery of respiration and is itself, of course, kept alive by the products of the very mechanism it controls. This mechanism consists of all the muscles of respiration—those which lift the ribs, the diaphragm and many other so-called accessory muscles. They all have to be finely co-ordinated by means of nerve impulses which begin in the brain, pass down the spinal cord and out to the muscles. Information of many kinds comes along sensory nerve pathways to the respiratory centre so that breathing can be automatically adjusted to the changing needs he moment. In order that life may continue re must be:

(1) a functioning breathing mechanism to revitalise the blood; and

(2) a circulation to carry the revitalised blood to the brain and other tissues.

many cases when breathing stops and uncon- usness supervenes as brain function is depres- , the heart will go on beating for some time ger. The aim of First Aid is to restore the athing by artificial respiration *before the heart ps.* Once the heart stops—and it eventually s so abruptly and without warning—the brain lead within the usual few minutes unless *both* heart and the breathing are restarted; and is a very much more difficult proposition n artificial respiration alone.

'or these reasons, a patient whose breathing stopped must have it started again without delay. Here, as in the case of severe haemor- ge, it is no use telephoning the doctor or even ting the patient in an ambulance. The First er must act himself, because he is on the spot the only one in a position to save life. Both ions require elementary First Aid training, even school children can accomplish them if y have been well taught.

sphyxia is the name given to a failure of the gen supply to the brain and is due to a break- m in some part of the complicated breathing hanism outlined above. One of its chief ses is a blockage of the airway by (*a*) solids (*b*) liquids. Any foreign body of the right pe and size will block the airway, as also will tongue in the unconscious patient. Re- nber how much more easily the child's airway become blocked because it is so much smaller. ckage by a liquid, is of course, drowning. nember that if a patient drowns in the entire an, it is only about half a cupful which is ng him any harm—as it only takes this amount ll the airway. The same goes for the amount ea, or vomit, required to kill an unconscious ient if it gets down the "wrong way"—as it unless someone prevents it.

nother very common cause of asphyxia is bon monoxide poisoning. Carbon monoxide lethal component of car exhaust fumes, in- pletely burning and badly ventilated fires stoves, and domestic coal gas. One of the nvenient properties of haemoglobin is that ombines with carbon monoxide very much e eagerly than with oxygen. Prolonged tact with even a very slightly contaminated osphere can build up a concentration of carbon oxide in the blood which will prevent the od from carrying sufficient oxygen—and this fact how it kills. It takes a very short time this to happen if the atmosphere is heavily taminated. Remember the danger of even ry slight leak of the gas either in the kitchen, nto a car from a faulty exhaust pipe or silencer. y elderly people die of coal gas poisoning y day because their sense of smell is poor and do not detect the leak.

ther causes of asphyxia are lack of oxygen he atmosphere, as occurs at high altitudes; hing of the chest so that the ribs cannot e; paralysis of the muscles of breathing by rference with their nerve supply, usually in t Aid, as a result of a broken neck and con- ient damage to the spinal cord (poliomyelitis occasionally produce the same effect by cking the nerves just before they leave the e); and depressing the respiratory centre in brain, most commonly nowadays by barbitur- poisoning.

ne only really effective method of artificial iration, which all members of any civilised munity should be able to carry out, can be ned in half an hour at a good First Aid class. is the direct, mouth-to-mouth method, etimes dramatised by journalists as the "kiss fe." The method is taught with the aid of els and cannot be satisfactorily learned by reading about it.

In discussing asphyxia, we have again had to consider the particularly vulnerable situation of the brain.

Fractures.

Broken bones are not the most serious possible consequences of injuries causing fractures. It is usually more to be feared that further damage will be done by the broken ends of the bones to tissues and organs in the neighbourhood of the fracture. The First Aid treatment of immobilising the part before transporting the casualty is designed to avoid this.

Six types of fracture are commonly taught, but some of them may co-exist in the same injury and the division is only for descriptive purposes. In addition there are two special fractures of the skull.

A "simple" or "closed" fracture is where only the bone is broken, without damage to surrounding tissues and without a wound. A "compound" or "open" fracture is one in which air, and hence germs, can get at the broken bone. This may be through a wound, in whose depths lies the broken bone; or the bone may have been pushed out through the skin; or a bullet track may lead down to the fracture. All these are examples of compound fracture and the great danger is that the bone will become infected. Even now that infections are less feared than before the days of antibiotics, it is still a grave matter for bone to get infected. However the antibiotic is given, we rely on the blood supply to carry it into the infected tissue, and bone has only a very small blood supply. If the infection is not successfully treated it can smoulder for a long time and become a "chronic osteomyelitis" which might ultimately necessitate amputation of the limb—and all because the original fracture was compound or open.

A "complicated" fracture is one in which the broken ends of the bone have damaged some important organ or tissue in the region. For example, a complicated fracture of the ribs is one in which the lung tissue, close behind the inner surface of the rib, has been pierced, and the patient will be coughing up small amounts of bright red, frothy blood. A "comminuted" fracture is one where the bone is broken into several pieces, and an "impacted" fracture is one in which the broken ends have been driven into each other and are firmly impacted. Finally a "greenstick" fracture occurs sometimes in children because their bones are not brittle and do not always break clean across. They partly break like a green stick.

"Depressed" fracture of the skull is where the vault of the skull has been struck and dinted. Many problems arise, since the brain is inevitably compressed and no dressing of the accompanying wound should be allowed to press on the brain. The dangers of infection here are not only to the broken bone, but to the meninges covering the brain, causing meningitis.

Fractured base of skull often passes through that part of the base through which the internal ear channel runs. Thus it frequently results in blood, or cerebrospinal fluid, or a mixture of both, emerging from the ear. The gravity of this fracture lies in the severity of the impact necessary to produce it, which will probably have also caused great destruction of delicate brain tissue. The outlook is usually very poor.

Remember that most casualties with fractures will require a general anaesthetic on arrival in hospital so that their fracture can be set in plaster or otherwise treated. Avoid giving them things by mouth such as drinks, which will mean a three-hour wait before anaesthetic can be administered.

Burns and Scalds.

The severity of a burn or scald depends largely on its surface area. If a patient dies of a burn, the cause of death is either infection or shock, the latter being due to fluid loss from the surface. Both hazards depend on surface area, since the bigger the surface the more germs are able to enter, and the more fluid can be lost. It follows that the small burn on the hand or arm is seldom a threat to life, however deep the injury; and we shall therefore confine our attention to the larger burns of the whole surface of the limb or trunk. Smaller bodies have a relatively larger surface area, and so a burn of the surface of a child's limb or trunk represents an even greater risk from fluid loss than a corresponding burn in the adult. Everyone has seen the fluid form in the blister of an ordinary small burn. It comes from the fluid part or "plasma" of the blood stream and the loss into such a blister may amount to a thimbleful. This will not hurt anyone. But the loss of similar fluid from the surface of a large burn may amount to many pints. The resultant shock will be partly due to this fluid loss from the blood stream resulting in a reduction in blood supply to the brain. Thus shock from burns has common features with shock from haemorrhage, and it is treated similarly, by transfusion. This time it is not a transfusion of blood but of plasma or some plasma substitute. In practice it is not only water that has been lost but a number of important chemicals dissolved in it as well, so that transfusion solutions have to contain sufficient of each individual substance to restore the deficit. The arrangements for replacing the lost materials are complex and urgent; every bit as urgent as after a haemorrhage and for the same reason. The brain cannot be left too long in need. In general, the First Aid treatment of burns of large surface area is to keep them clean with a dry dressing and get them very quickly to hospital. Life-saving treatment by transfusion cannot start until they arrive. The only permissible delay is in the case of burns caused by corrosive chemicals which must be thoroughly washed off before transport, so that they do not continue to burn the patient on the way.

Unconsciousness.

It is not sufficiently appreciated that the dangers of being unconscious can often far outweigh the dangers from the cause of the unconsciousness. For example it is known that as many as half the deaths from head injuries are due to the airway becoming obstructed and not to the injury itself. The most important thing in managing the unconscious patient from any cause is to preserve an airway. Particularly if the patient is lying on his back it is likely to get blocked:

(*a*) by his own tongue as the lower jaw sags backwards;

(*b*) by his dentures (so remove them);

(*c*) by vomit; and

(*d*) by anything anyone may be tempted to give him by mouth.

Nothing whatever should be given by mouth in any circumstances to the unconscious patient, since he cannot swallow and it will inevitably go into his lungs.

Many of these dangers can be very much reduced by not having him on his back. Place him instead in the semi-prone position: half on his side, half on his front, with the upper leg drawn up to prevent him from rolling about. In this position the head will be inclined downwards. The jaw will tend to sag forwards and the tongue with it, away from the back of the throat. Any vomit will also come forwards. If the tongue does get in the way of the breathing the airway can usually be cleared by bending the head backwards as far as it will go and pushing the whole lower jaw forwards, by pushing from behind the angle of the jaw on both sides.

DRUG ABUSE AND DRUG DEPENDENCE.

This section of earlier editions of *Pears* was simply called "Addiction." This word is still much used, but is gradually being replaced by the terms in the present title, because ideas about the nature of the problem and methods of dealing with it are changing. Addiction is a word that conjures up rather 19th century ideas in the minds of readers: opium dens, inscrutable orientals, Sherlock Holmes injecting himself with cocaine—basically a phenomenon of foreign origin, rather frightening if its implications were not literary rather than factual, and not of great significance in Great Britain.

Drug Abuse.

It is now realised by doctors, research scientists, social workers, and the police—if still not by society as a whole—that the truth is quite different. The *abuse* of drugs in this country is at present of large proportions, increasing rapidly and showing no signs of diminishing. It is responsible each year for thousands of deaths by suicide and by accidental overdosage; for an enormous but virtually unmeasurable amount of private suffering; and for the loss to society, in terms of reduced working efficiency, of millions of man-hours every year. It has nothing to do with opium smoking which was never in any case more than the eccentricity of the few. Opium is virtually unused in medicine these days and the amount of smuggling, always small, is now negligible. The problems today arise chiefly from the misuse of drugs given by doctors for their effects on the central nervous system—the pain-killers, sleeping pills, "stimulants," and "tranquillisers."

Drugs and Medicines.

To the doctor, any substance is a drug that can be introduced into the body from outside, and that is capable of producing some detectable effect. Most such substances have a beneficial use. They are "medicines," and as such are given by doctors in suitable cases. Others, for example, nicotine (in cigarettes), alcohol (in beer, wine, or spirits), and carbon monoxide (in coal gas), are of doubtful benefit and of certain harm and are used by doctors, if at all, only under certain very special and usually experimental conditions.

Medicines may be classified under four main headings. First, there are those like quinine, or penicillin and other so-called antibiotics, that actually cure diseases by eradicating the organism (bacteria or other parasites) that cause disturbance of normal bodily function. Second, drugs such as insulin or the steroids overcome in the unhealthy the lack of some necessary substance a healthy body manufactures for itself: they must usually continue to be given for life. Third are the drugs which relieve the signs of disease—for example, there are many new drugs that lower the blood pressure or increase the output of urine—without being able to put right the disturbed basic situation which is the cause of the trouble. Fourth are drugs to relieve the patient's symptoms—which make him feel better, less breathless, take away his pain, help him to sleep, and so on—although we seldom know why they are able to do this. Indeed, in many cases we suspect that they are acting mainly as a token of help from doctor to patient, and so encouraging his body to fight a more successful battle on its own behalf. (There is in fact a fifth class of drugs, which includes the majority of those on the market at any time, the members of which are devoid of any action whatsoever except that of enriching those who manufacture and sell them; but we are not concerned with these at the moment. They constitute a related, but different, kind of problem.)

There is no doubt that the genuine advances in beneficial drugs during the last thirty years have been enormous; but the very successes of the penicillins, tetracyclines, antimalarials, hormones, and so on have bred in the public and in the medical profession itself an attitude of uncritical wonder. There have been relatively few drugs in the first and second categories mentioned above; and in the field of mental health, the importance of which is now so rightly emphasised, there are virtually none. Yet drugs which ac the brain are often received as if they were ive although they may pose fresh problems r than solve the old. Thus, although there nany drugs which act upon the mind, few nis in any fundamental sense: they relieve and anxiety, bring sleep and lessening of s, and may allow the patient to recuperate elf during the relief they provide. But often deeper change does not occur—sometimes use the doctor has not clearly seen his part in ng to bring it about—and then the sympto- c relief may come to be sought for its own

w and old drugs are still prescribed for their s upon the mind—less so now than even a years ago, before the thalidomide disaster— out sufficient attention to possible long-term ers, of which there are in effect four.

ers of Long-term Medication with Drugs ing on the Brain.

Toxic effects. Drugs which act upon the ous system, like any others, have character- toxic or unwanted effects of their own lentally, these may become apparent rapidly; on rare occasions, after only a single dose). effects may have little or nothing to do with desired effects for which they are being ribed and taken. For example, it has only to be realised quite recently that aspirin ble to cause bleeding, which is occasionally us, from the lining of the stomach in a large rtion of people who take aspirin regularly; hat phenacetin, another substance very ently present in pain-killers that can be nt from chemists without prescription, (after prolonged use) to kidney damage. drugs may cause rashes and other allergic ions in susceptible subjects; and jaundice, ng, tremors, and motor disorders are known cur in some patients taking a variety of drugs.

' *Rebound.*" The body works in such a way, a variety of its activities, that it tends to n to a "neutral" position after it has ted from this for any reason. For example, eating tends to be followed by a lessening petite, at least for a time; the runner makes r his air-deficit during the race by breathing deeply thereafter; and if, at rest, you he for a time more rapidly and deeply than eed, this period will be followed by one in you breathe *less* often than usual until alance is restored. These illustrations—and are others—have nothing to do with drugs: n a similar way, it seems that if a continued or an unpleasant emotional state such as ty or depression is changed into its opposite, noved altogether by the use of a drug, the state may return with increased force when rug is no longer taken. The "rebound" menon, naturally, encourages the patient e another dose, and so on.

Iabit formation. This alternation of mood- ed-by-drug with the disturbed mood itself o the habit of taking the drug. The patient to rely upon it and to take it anyway, even the unpleasant state has returned. At age he is said to be "habituated": he has chological need for the drug, and later may e disturbed at the possibility that it will e available when he needs it. This might atter so greatly, if it were not that continued drugs in this way has physical consequences l.

'olerance and habituation. The body also to restore its own balance when drugs are too. It "learns" surprisingly quickly o deal with substances with which it has before been confronted, so that it eliminates uent doses more and more quickly and etely. Thus the effect of each successive smaller and lasts for progressively shorter s of time. To counter this, the patient tends to increase the dose: and the vicious circle continues. At this point he has become physically dependent upon the drug: and he may suffer physically—sometimes so severely that he dies—if supplies are not continued.

As he increases the dose in this way, so his tolerance of its effects increases, to such an extent that after prolonged use he may be taking doses of a drug that are five or ten times greater than those which will kill somebody not dependent upon them in this way. It sometimes happens that a patient develops a renewed craving at some point after a course of treatment, in which the dose of drug has been reduced without removing the underlying cause of his dependence. He may then obtain and use the dose he habitually took before treatment, not knowing that his body will have lost its tolerance of such doses. That dose is now as high for him as for any other person and so may be lethal. There has been a number of deaths for this reason.

Factors in the Causation of Dependence.

The risk of becoming dependent upon a drug is governed by three main factors: the drug itself, the personality of the individual who takes it, and the circumstances in which it is taken. Most adults have taken alcohol at one time or another, unless it is against their code to do so; yet *relatively* few are dependent upon it (relatively few, but many too many: perhaps half a million in the United Kingdom alone). Many of us have had morphine or some other strong pain-killer for medical reasons, without becoming dependent upon it (whatever so-called addicts say, it is extremely rare for anyone to become dependent on an opiate because he was introduced to it in a medical setting). On the other hand, if we start to take such a drug "for kicks"—as more and more people, particularly teen-agers and young adults are doing—it is extremely probable the we shall become dependent upon it, and sooner rather than later at that. It is also probable that each one of us would become dependent, were he obliged to take it regularly, for long enough, and in sufficient dosage. Thus, although there are personalities—psychopathic, immature, or unstable—that are more prone than others to become dependent if they are exposed to the drug, there are also drugs that are more likely than others to cause such dependence no matter to whom they are given. The extent of the dependence will vary: with some, it is never physiological but remains psychological (but not the less real or disturbing for that). Also, the rate at which dependence develops may vary; and the picture presented by the dependent subject—the extent to which his normal life is impaired, or to which he becomes dangerous to himself or others—varies as well. In a very much oversimplified way, some of these relationships will now be summarised for certain substances.

Heroin, morphine and cocaine are usually injected. Barbiturates (sleeping pills) and Amphetamine ("Benzedrine") are tablets or capsules, and Marihuana ("reefers," hashish) is smoked in cigarettes. Heroin and cocaine are now usually taken together. Combinations of drugs often act differently from their individual constituents and patients dependent upon them are even more difficult to treat. Barbiturate and amphetamine, also, are often mixed (as in "purple hearts"). There is considerable *psychological* dependence on heroin, morphine, cocaine, and amphetamine, but much less with marihuana. *Physiological* dependence is great with heroin and morphine, less with barbiturates, alcohol, and amphetamine in that order, and virtually nil with cocaine and marihuana. Personality plays a greater part in initiating dependence on alcohol, marihuana, and barbiturates than with the others. Heroin, cocaine, and morphine are the cause of more antisocial tendencies in dependent people than alcohol, barbiturates, and amphetamine. The chief danger of marihuana (mere possession of which is illegal) seems to be that the search for it will lead the searcher into localities where his risk of exposure to even more dangerous influences is greatly increased. It is thus sometimes argued that if it were legal to consume marihuana, the number of young people who yearly become dependent upon the other more dangerous drugs would in fact decrease. There is as yet no evidence for or against this proposition. The number of drug dependent people in U.K. is rising fast for heroin and cocaine. This number is very large for alcohol, and is increasing in the case of barbiturates and marihuana. Very few people are dependent on morphine, and the number is not growing.

Treatment.

Exhortations, imprisonment, and other moralistic or legalistic approaches are useless. Treatment of any person dependent upon a drug is a matter for a qualified psychotherapist. It is liable to be time-consuming and frustrating for patient and doctor, and it is frequently unsuccessful. At present, there are too few specialists or centres where treatment can be obtained, although it is to be hoped that this situation will change as the problem is increasingly seen by our society to be of exceptional gravity.

When there is little or no chance of cure, prevention is certainly the best treatment. Drugs should only be taken on the prescription of a doctor: and the patient should remind him from time to time, if this be necessary, that he would like to dispense with his drugs as soon as the doctor thinks it possible. It should also be remembered that there is often no need to reach for the aspirin (or any other drug that anyone can buy from the chemist without prescription) at the first sign of a headache—or to reach for it at all to help one sleep or relax, for which purpose such drugs are in any case pharmacologically useless. A wait for ten minutes is good discipline, and will frequently resolve the problem to an extent that makes a drug unnecessary.

DISEASES OF THE BLOOD

INTRODUCTION.

There are about eight or ten pints of blood in the adult human body. Its main function is to transport nutrient materials to all the various tissues and to carry waste products of tissue activity to organs such as the lungs, kidneys, and liver for disposal. It also helps to maintain a constant chemical environment for the body cells, some of which would be very disturbed in their function if the correct balance of organic and inorganic chemicals were not maintained. The blood also serves a protective function in fighting disease, either with certain of the white cells, or by means of immune antibodies dissolved and carried in the plasma.

A little more than half the volume of blood is the fluid plasma, in which are dissolved all the nutrient materials, organic and inorganic chemicals, hormones and large quantities of protein. The remainder consists of red cells, white cells, and some particles which are not really cells, called platelets. In every cubic millimetre of whole blood, or in every droplet the size of a pin head, there are about 5 million red cells, between 5,000 and 10,000 white cells, and 200,000 platelets as well as half a cubic millilitre of plasma. The red cells suffer a great deal of wear and tear as they are hurled round the circulation, and they only survive for three or four months. There is a red cell factory in the bone marrow which replaces them at exactly the rate they are destroyed, and you have made very many millions of new ones while you have been reading this single paragraph. The function of the red cells is to carry the oxygen from the lungs to the tissues, and to play an important part in carrying the waste gas, carbon dioxide, in the reverse direction. A shortage of red cells, and hence of their oxygen-carrying pigment, hæmoglobin, is called anæmia; an excess is called polycythæmia.

There are five kinds of white cells or leucocytes: neutrophils (or polymorphonuclear leucocytes), eosinophils, basophils, lymphocytes, and monocytes. The first three are quite actively moti
like amœbæ, and are capable of ingesting bacte
and other particles by "phagocytosis." Th
is a great increase in the number of neutrophils
leucocytosis) during bacterial infections and oth
inflammatory conditions like appendicitis. Eosi
phils are found in larger numbers than usual
allergic conditions like asthma, and in infestatio
by worms and other parasites, but we do not kn
why this should be. Lymphocytes are concern
with the manufacture of antibodies. In so
infections, particularly tuberculosis and vi
infections, there are fewer white cells than us
(leucopenia). Pus consists of the dissolv
remnants of inflamed tissue and many de
neutrophils which have become casualties in t
battle against infection. It also contains surv
ing bacteria, and as such is a source of furth
infection.

Platelets are curious particles, smaller than a
of the cells. They are little pieces broken
certain special bone-marrow cells which produ
them. They have a role in the stemming of blo
loss after injury, partly because they are stic
and adhere to one another and to broken blo
vessels and help to plug the open ends of damag
vessels; and partly because they contain a gre
deal of a substance (thrombokinase) which
necessary to the clotting mechanism of the bloo

Hæmatology, as the study of blood and
diseases is called, is a very complicated subj
and only a brief general account will be giv
here. Diagnosis is usually made by taking sm
samples of blood (or of the bone marrow whe
blood cells are made), counting the numbers of t
different cells and examining their appearan
under the microscope. We shall briefly consi
the main diseases involving red cells, white ce
and platelets.

Red Cell Diseases.

These are of two main groups leading to
shortage of red cells (anæmia), or an exce
(polycythæmia). The former is much the mo
common and there are many different kinds.
all of them the shortage of red cells results in
depletion of the capacity of the blood to car
oxygen. This means that the heart must wo
harder to send more blood than usual to t
tissues, and even so the tissues will often go sho
The patient will be persistently tired and listle
and if the anæmia is severe the action of the bra
and heart will be seriously impeded, even leadi
to fainting, cardiac pain, and breathlessness
exertion. All these symptoms, however, can
caused by many other conditions. The only w
to be sure they are due to anæmia is by a prop
examination of the blood, and even this will n
lead to the truth if the picture has been spoilt
the patient taking iron tonics and other remedi
of his own accord. Therefore do not dose yours
with tonics, in case you really have anæmia. Y
may make it impossible to arrive at a prop
diagnosis later.

Hæmorrhagic Anæmia. Anæmia, a shortage
red cells, may be due to a variety of causes, sing
or in combination. One very obvious cause
loss of blood, or hæmorrhage. Following the su
den loss of a pint or two of blood or more, the re
cell-producing bone marrow "factory" will st
up its production; but even if it is adequate
supplied with all the raw materials such as iro
it may well take many weeks to build up t
numbers to normal. A very severe degree
hæmorrhagic anæmia is usually treated by blo
transfusion. Milder degrees can be treated
taking extra iron, often over a long period of tim
The supply of iron for making new red-cell pigme
is nearly always the bottle-neck which lim
production. Hæmorrhagic anæmia can co
monly occur, however, without a sudden seve
hæmorrhage. From what has been said about t
constant replacement of red cells as they wear o
it must be obvious that even if there is only a slig
failure to keep pace with the numbers lost, seve

hs of such a failure can eventually deplete the
pers to the level of very severe anæmia.
situation is common when small amounts of
are being continuously or repeatedly lost,
here again it is a shortage of dietary iron
is the usual cause of the failure to replace the
ed cells. Normal menstrual loss in women
girls whose diet is on the border-line of iron
ency is a common cause of progressive tired-
and lack of energy. Where the menstrual
is heavier than usual, or where it is frankly
sive in older women due to the various
non gynæcological disorders, serious anæmia
rprisingly common. During pregnancy a
deal of iron is lost by the mother to the
, and this, together with the inevitable blood
at delivery, often makes for a very tired
er indeed, just at the time when there is an
nous amount of work to be done to manu-
re milk and attend to all the extra household
of baby care. For these reasons it is
st routinely advisable to build up stocks of
throughout the pregnancy by remembering
ke the pills provided. Men as well as women
ose small amounts of blood continuously in
life from gastro-intestinal conditions such as
ulcers, and tropical infestations such as
worm; and here again the anæmia may be
as severe in the long run as that which in-
bly follows a sudden, massive hæmorrhage.
extra word of warning. Do not assume
se you are pale that you are anæmic. Pallor
ery poor guide, because it is dependent on so
other things, like the blood vessels in your
and its thickness and translucency. Nothing
blood test (which is so easy for your doctor
can really tell you if you are anæmic. And
r anæmia is due to a blood-losing condition,
that too must be treated. So do not be
ted to treat yourself, and never delay seeing
doctor about any excessive or unexplained
ing, from any source.

molytic Anæmia occurs when for any reason,
are more blood cells than usual being de-
ed in the body. This may be because the
are abnormally fragile, or because normal
have been attacked by something to which
re allergic, or rarely because you have be-
sensitive to your own red cells. Sometimes
n babies have severe hæmolytic anæmia, due
incompatability of blood group (Rh factor)
en the mother and the baby, and the same
of thing happens if incompatible blood is
by mistake in blood transfusion. Up to a
in mild hæmolytic anæmia, the bone
w can keep pace with the increased loss of
but beyond this point anæmia develops.
incompatible blood transfusions a very dan-
s situation results from the effects of the
ction of red cells and the liberation of their
cts into the blood. One form of jaundice is
produced in hæmolytic anæmia, the patient
ning yellow because of the breakdown pro-
of red cells circulating in excess as bile
nts. These latter are normally always
t to a small extent due to the normal, com-
vely small, rate of destruction of effete red

astic Anæmia is the term given to anæmia
a virtually total failure of the bone marrow
ll factory. Sometimes this occurs for no
s reason. It is sometimes due to a heavy
f radioactivity or X-rays knocking out the
f the "factory." It may even be due to
cells growing in the bone marrow cavity
t leaving sufficient room for the red marrow
It is fortunate that aplastic anæmia is very
because it can only be treated by blood
sions every few weeks for the rest of the
t's life. Very occasionally there have been
ions to this rule, when the patient's marrow
e-awakened for no apparent reason and
ly begins to make red cells again.

icious Anæmia. This is a fairly uncom-
næmia, which has a very interesting story.
ocesses by which red cells are manufactured
are many and complex, and depend, like so many other bodily activities, on the supply of a vitamin containing cobalt, called vitamin B_{12}. This is nearly always present in more than adequate quantities in the diet, but in order for it to be absorbed from the intestine, there must also be a substance called "intrinsic factor" which is normally made by the lining of the stomach. People with pernicious anæmia have suffered a degeneration of the lining of their stomachs, probably because, for some reason, they have become "sensitive" to this part of their own tissue. This kind of civil war within the body is known as an "auto-immune" disease, and is comparable in type with some forms of hæmolytic anæmia. In other words they destroy their own stomach lining, fail to produce "intrinsic factor," and as a result fail to absorb vitamin B_{12} into the body. Faced with a failure in the supply of this essential substance, the bone marrow produces too few red cells, and the few that are produced are deformed, much too large, and very fragile. In addition to its role in blood formation, vitamin B_{12} is essential to the normal functioning of the spinal cord, and in long-standing cases of untreated pernicious anæmia, there is often a resulting neurological disability.

The cure for pernicious anæmia was discovered about forty years ago, and is a triumph for the scientific investigation of the causes of disease. While treating anæmic dogs, an American scientist named Minot discovered that eating raw liver in large quantities produced a tremendous improvement. Patients with pernicious anæmia were then made to eat vast quantities of raw liver—about one or two pounds a day—and were found to get better, whereas previously they had inevitably died. Raw liver is, of course, very unpleasant to eat, and after a few years it was found possible to prepare crude extracts for injection. Injection had the great advantage that no absorption difficulties arose, and much less liver could be used. Biochemists then began the enormous task of trying to find which of the thousands of substances in liver was the vital factor, and after many years of painstaking chemical fractionation of liver and trying out the various fractions as a cure for the disease, vitamin B_{12} was discovered. The pure substance is one of the most powerful substances known, being active in amounts as small as millionths of a gram. Nowadays pernicious anæmia is treated by small occasional injections of the vitamin, whose other name is cyancobalamin.

Polycythæmia. Too many red cells per cubic millilitre of blood can be found without there being an increase of the total number of red cells in the body. This occurs in dehydration, when there is a loss of plasma without a comparable loss of cells, and is called hæmo-concentration. Alternatively, the bone marrow can manufacture more cells than usual as a response to living for long periods at high altitudes. The beneficial result can be that the blood can carry normal amounts of oxygen, even though the supply (in the rarefied air) is reduced. Finally there is a red cell disease, analagous to leukæmia (*q.v.*) in which the bone marrow factory gets out of control and produces too many cells with no beneficial results. The number in the blood can be double the normal and the blood becomes so thick that the heart has difficulty pumping it round the body. This disease (*polycythæmia rubra vera*) used to be treated by repeatedly bleeding the patient to reduce the numbers. It is now treated very successfully with carefully judged amounts of radioactive phosphorus or certain other "anti-mitotic" chemicals which reduce the rate of multiplication of bone marrow cells. Care has to be taken not to knock them out altogether, in which case aplastic anæmia or agranulocytosis (*q.v*) could result.

White Cell Diseases.

These are fortunately much rarer than diseases involving red cells, and are usually much more to be feared.

Agranulocytosis. In this condition the number of those white cells which are responsible for phagocytosis of bacteria falls precipitously. The result is that one of the main bodily defences against infection fails, and the patient may die from an overwhelming invasion of germs and the accompanying high fever. The usual cause is abnormal sensitivity to certain drugs, often those which are in widespread use and only give trouble in the occasional case. One example among hundreds is the antibiotic chloramphenicol which specifically kills typhoid bacteria and is used for that purpose. It is believed that about one case in 60,000 becomes sensitive to it and agranulocytosis often fatally follows. The fact that almost any drug *can* do this to some people and yet be quite safe for the majority, is one good reason not to dose yourself unnecessarily with over-the-counter medicines.

Leukæmia. This is a cancer of the white cells, in which the normal rate of production of any of the white cells gets out of control, leading to a pile-up of abnormal cells at the site of production (bone marrow, lymph nodes, and spleen) or in the blood, or both. In spite of an increase in their numbers, their abnormality renders them unable to combat infection; sepsis and fever result. It is known that this kind of cancer can be caused by the effects of ionizing radiation on the white-cell factory, and it is certain at least in animals, that viruses can also be responsible. Survivors from the atomic explosions in Japan have subsequently suffered from leukæmia far more commonly than the rest of us, as have doctors, nurses, and patients who have been over-exposed to X-rays. At the time of writing, leukæmia is still a uniformly fatal disease, although patients may sometimes survive many years. Their remaining time can nearly always be made more comfortable by various forms of treatment, and one day a cure will be found by the research workers devoting their time to its study. It is difficult not to get very impatient with the slow rate of progress of these studies, particularly when caring for children and young people whose lives are inevitably ended by the disease. The solution, however, as with other forms of cancer, probably depends on the understanding of the nature of life itself, and as long as biological research remains short of the relatively small amounts of money required to tackle these problems at reasonable speed, we have no right to be impatient, except with our elected leaders who spend far more than is needed on less important things.

Hodgkin's Disease, Lymphosarcoma, and Reticulosarcoma. These are cancerous diseases in many ways similar to leukæmia, in which the cancer process involves cells of the so-called reticulo-endothelial system. Such cells are principally in lymph nodes (which used to be called lymph glands) and the spleen. Hodgkin's disease is named after one of the more illustrious pathologists at Guy's Hospital who first described it nearly a hundred years ago, and whose early specimens of affected lymph nodes are still preserved there; is an even greater puzzle than leukæmia. There are all grades of severity, and although many patients die within six months, many survive much longer, even for twenty years in some cases.

Hæmorrhagic or Bleeding Diseases.

Whenever blood vessels are damaged by injury, there is a remarkable series of mechanisms which automatically come into operation to stem the flow of blood. There is a constriction of all the smaller vessels in the locality. Platelets stick together and release substances which help the vessels to stay constricted as well as others necessary to blood clotting, and yet others which help to bind the clot tightly together. Later, materials appear to prevent too much clotting, and eventually the clot is removed altogether as healing proceeds. There are some very complicated diseases of this blood-conserving mechanism which can lead to abnormal bleeding, sometimes beneath the skin to produce bruising or even smaller leak
sometimes leading to a greater loss of blood, pa
ticularly following a wound. In some kinds
purpura (bleeding tendency) the blood vessels a
the cause of the trouble, having become frag
and leaky for a number of reasons. This happe
in old age (*senile purpura*), in scurvy, or vitamin
deficiency, as an occasional accompaniment
infective diseases, or as an immunological effect
the lining of blood vessels when the patient b
comes sensitised to certain substances (*Schönlei*
Henoch or *anaphylactoid purpura*). The latt
often follows a streptococcal sore throat, just
rheumatic fever and acute nephritis do; and
well as the purpura there may be joint pains a
nephritis. Just as almost any drug or chemi
will cause agranulocytosis in some people, so
can also cause anaphylactoid purpura.

Purpura may also be due to a lack of platele
known as thrombocytopenia (a shortage
thrombocytes or platelets). This can happen
the bone marrow factory is depressed, since this
where platelets too are made. It is therefore
common accompaniment of leukæmia or aplast
anæmia. Or there can be increased destructi
of platelets in some diseases of the spleen. Plat
lets normally last eight to ten days, but their li
span can be shortened in heart failure, and follo
ing massive transfusions, or often for no appare
reason ("idiopathic" thrombocytopenia), wh
removal of the spleen can sometimes help.

Finally, defects of the *clotting mechanism* w
lead to a bleeding tendency, and since the mecha
ism itself is very complex, so is the variety
things which can upset it. The liver provides t
blood with many of the substances required f
clotting, so it is not surprising that a clotting defe
commonly accompanies liver disease. One nece
sary substance for blood clotting is called "an
hæmophilic factor" and is missing from peop
who have inherited the disease *hæmophil*
These unfortunate people may die of hæmorrha
from quite small cuts or minor surgical procedu
like tooth-extraction, and although it is possible
prepare antihæmophilic factor, it is not yet po
sible to give continuous, life-long treatment wi
it. In emergencies a transfusion of fresh blo
(the factor is destroyed by storing) is sometim
used.

DISEASES OF THE HEART AND BLOOD-VESSELS.

INTRODUCTION.

The heart consists of about three-quarters of
pound of muscle, which makes up the walls of
four chambers. Anatomically the human hea
closely resembles the sheep's hearts to be fou
in a butcher's shop. Indeed it would be an
structive exercise to dissect one of these in t
order described below, since there is no other w
of properly appreciating what the chambe
valves, etc., are really like. There are two qu
separate pumps in the heart—one on the owne
right (or on your *left* if you are looking at the fro
of someone else), and one on his left. The rig
heart collects spent, deoxygenated, "venou
blood which returns there from the whole of t
body, and gives it the comparatively small pu
required to drive it through the adjacent lun
The left heart collects the revitalised, oxygenat
"arterial" blood as it trickles away from t
lungs, and gives it the enormous push required
build up the arterial blood-pressure, so that it c
be forced through all the tissues of the body.
may be expected, the right heart chambers ha
much thinner walls than the left, since their mus
has much less work to do. This will help you g
your bearings with the sheep's heart. The t
or apex, is the lowest part. The thick-feeli
side is the left, the thin the right; and the gre
vessels are at the top.

The upper chamber on the right, or right atriu
has two large openings into it through which

spent blood arrives from the upper and lower
at veins (the superior and inferior venae cavae).
open the thin wall of the right atrium with
sors between these two holes to lay open the
erior of the chamber, noting the "auricle" or
og's ear" that forms a small cul-de-sac. The
le chamber is sometimes, inaccurately, called
auricle. You should be able to push a finger
nwards into the lower chamber—the right
tricle—through a communicating hole guarded
the three thin cusps of the *tricuspid valve*.
se will not obstruct your finger, since they are
gned to permit blood flow in the same direc-
. When the atrium is full of blood, it squeezes
contents through the tricuspid valve into the
t ventricle; and when, a split second later,
ventricle is full and contracts, the three cusps
e together to prevent the blood from flowing
kwards into the atrium again. Instead the
t blood is driven onwards through the *pul-
ary valve* (in the upper part of the right
tricle), through the pulmonary artery, to be
vered to the lungs. The pulmonary valve has
e very well-defined cusps which prevent blood
n coming back into the ventricle as it relaxes
eceive more blood from the atrium before the
t contraction or beat. It is possible to pass
ade of the scissors from the opened-out right
um, through the tricuspid valve towards the
of the heart, and cut along the right border of
heart through the thickness of the ventricular
cle. Then cut upwards again, passing the
sors blade through the pulmonary valve and
n up the *pulmonary artery*. If you have done
successfully you will have followed the path
n by the spent blood through the right heart
he lungs. Notice the thick round bands of
cle lining the ventricle, and notice too that
have not entered the left heart, which has no
nection with the right except in some congeni-
malformations (see later). The same dissec-
can now be made of the left heart. Open up
left atrium, noting its "dog's ear" or
ricle," pass the scissors down into the *left
ricle* through the two rather flimsy cusps of
mitral valve. Notice how much thicker is the
cle of the left ventricle, and cut upwards
ugh the three well-formed cusps of the *aortic
e* into the main artery of the body—the *aorta*.
aorta as it leaves the left heart is distinguish-
from the pulmonary artery as it leaves the
t, partly by the extreme toughness of the
ic wall (it has to withstand so much more
d-pressure); and partly by the entrances or
ces of the two small branches given off by the
a, just beyond the valve cusps, which go to
ly the heart muscle itself with blood. These
the *coronary arteries* which are so necessary
he heart's own survival.

e amount of blood pumped in unit time, or
cardiac output, can be varied a great deal,
rding to the needs of the moment. This is
mplished by altering both the heart rate and
stroke volume, the amount expelled per beat.
y minute, the healthy adult man at rest
s about ten pints of blood through the heart—
mount equivalent to all the blood he possesses.
n exercise is taken, or in response to anxiety
ar, this is stepped up many times, so that the
cles can receive a greatly augmented supply
e materials required for action. The con-
ing mechanisms which allow these changes to
nade automatically are partly organised in
brain by the so-called *cardiac centre*; and
y by local mechanical and chemical stimuli
e heart muscle itself. The cardiac centre is
nuously receiving information through nerves
t the physical and chemical state of the
lation, and also from the mind; which is
y how certain emotions make the heart beat
r. All the information is integrated, and a
ac output continuously arranged which is
opriate for current demands.

rdiac Neurosis. In ordinary circumstances
st, most healthy people are not conscious of
heart-beat. However, there are many per-
healthy people whose hearts slip in an extra
occasionally. Sometimes their owners are
of this, and become unnecessarily alarmed.
Their fear causes palpitations (a pounding of the heart) and the tension mounts. An undue anxiety about the tricks played by a healthy heart sometimes leads people to interpret minor pains in the chest, or even indigestion, as grave symptoms of heart disease, and the consequent anxiety leads to still worse symptoms. If you are one of these worried people, take your worries to your doctor, and let him decide for you whether there is anything wrong. A hundred to one there isn't, and then you will have to find something else to worry about, or better still give up the habit altogether. Many people secretly worry about heart disease and high blood-pressure for years, when very often they are worrying unnecessarily. Even if there is cause for worry, so much can be done for these conditions (as it can for cancer) provided medical advice is taken early in the course of the disease. Remember, too, that the slight feeling of giddiness when you get up suddenly from having been lying down, is often experienced by most normal people; but if you get frightened by it you will begin to breath more quickly and deeply: and this in itself will make you feel even more faint—and so on.

Heart Failure. When the cardiac output of blood is too little for the requirements of the body, a state of *circulatory failure* has arisen, and when this is due primarily to the heart itself being at fault, it is more properly called *heart failure.* As will be seen, heart failure is not a disease, but the common result of a large number of different diseases. The signs and symptoms produced are caused by two sorts of process: (*a*) tissues of the body have too little blood flow through them and are therefore undersupplied; (*b*) blood accumulates and stagnates in tissues, causing congestion, since the failing heart cannot move forward the amount of blood presented to it in the great veins. Often the left or right side of the heart fails disproportionately. In *left heart failure* the lungs are congested because they are the territory from which the left heart is failing to move blood. The patient has great difficulty with his breathing, and in advanced cases may not be able to breathe when he lies down horizontally, because the lungs become so congested and waterlogged. In *right heart failure* the main veins are congested and other parts of the body become swollen with excess tissue fluid, mainly in the lower parts such as the legs and ankles. This swelling with fluid is called œdema, and in heart failure is only partly due to the mechanics of the failing heart. It is mainly due to a poorly understood retention of sodium in the body, a situation in which excess water is also retained. Whatever the type of heart failure, it is always likely to be a changing condition, since the amount of failure will depend as much on the demands being made as on the state of the heart. For instance, in mild cases at rest when the required cardiac output is small, there may be no signs or symptoms. These may only appear on exertion. Heart failure will be referred to again later under the various conditions which cause it.

Treatment of heart failure is quite logical. It is aimed at correcting the imbalance between supply and demand of blood, and at the removal of the accumulated excess fluid. We can therefore (*a*) reduce the body's demand for blood; (*b*) increase the supply or cardiac output; and (*c*) promote the excretion of sodium and fluid. Demand for blood is reduced by rest, both physical and mental, and by reduction of weight, since obesity (being overweight) is an additional demand on the cardiovascular system. The cardiac output can be increased by administering a "tonic" to the heart muscle in the form of *digitalis*, which is a powerful heart stimulant derived from foxglove leaf. Fluid (and hence salt) accumulation can be helped by restricting the intake of salt and by giving drugs which promote its excretion by the kidneys (diuretics). Very occasionally, very large accumulations of fluid in the legs, abdomen, or thorax, are tapped and drained physically, with needles. These remarks on treatment, as elsewhere in the Medical Section, are of course very general and must not encourage anyone to treat themselves for such a potentially serious condition as heart failure. Even such a simple measure as doing without salt can be practised quite unnecessarily by many people for years, simply as a result of reading a paragraph like the above. The most they accomplish is to make their food taste horribly dull. If you need to reduce salt intake you should be in your doctor's care, and so please let him decide.

Congenital Heart Disease. It has been estimated that of all the babies born who survive at least one month, there will be about one in every two hundred with some form of congenital heart disease; that is to say that the heart will have failed to develop properly in embryonic life. In some cases this is associated with a virus disease of the mother (commonly rubella, or German measles) or with certain drugs taken by the mother (e.g. thalidomide) at a time, very early in pregnancy, when organs are assuming their adult shape. Parents should see to it that their daughters get German measles before they grow up; and drugs of all kinds should be avoided where possible during early pregnancy. In most cases of congenital heart disease, however, there is no known cause, and it seems that the manner of formation of the embryonic heart is so delicate that it can be thrown out of gear very easily, perhaps even by chance. Scores of different types of defect occur, singly and in combination. Any of the valves may be anatomically defective—either failing to close properly (*incompetence*) or being too tight (*stenosis*); the great vessels (pulmonary artery and aorta) may be switched round, or *transposed*, so that they emerge from the wrong ventricle; there may be defects in the wall (*septum*) which separates the atria or the ventricles on each side (*septal defect*, or " hole in the heart "); or there may be a persistence of the vessel which in the fœtus normally by-passes the lungs by joining the pulmonary artery to the aorta (*patent ductus arteriosus*). This vessel normally closes at the time of birth when the first breaths are taken, and subsequently disappears, so that the whole output of the heart is then sent round the lungs. Detecting congenital heart disease early is one of the purposes of routine post-natal check-up examinations of the baby. Exact diagnosis requires very complicated techniques, and sometimes the structural defect can be corrected by surgery, with almost miraculous results.

Rheumatic Heart Disease. Acute rheumatic fever is not to be confused with other forms of rheumatism. Many tissues of the body (particularly the heart) are attacked, as well as the joints, and the trouble is due to a sensitivity which has developed to certain bacteria (*haemolytic streptococci*) which have probably caused a sore throat about three weeks before the onset of the disease. Why acute rheumatism only rarely follows streptococcal sore throat is poorly understood, but this is no consolation to the one per cent or so of the population whose hearts bear its scars. During the acute phase of the illness which usually occurs before the age of fifteen, inflammatory damage occurs to the valves, the heart muscle, and the sac in which the heart lives, the *pericardium*. So there is a *valvulitis* or *endocarditis*, a *myocarditis* and a *pericarditis*. There may be acute heart failure at this stage if the heart is severely affected. The better-known results of rheumatic heart disease, however, are caused in the ensuing years by scarring of the healed valves. The valves are thickened and deformed. They may have lost their elasticity and stretch, so that they do not close properly (*incompetence*); or they may contract and tighten (*stenosis*). In both cases the heart chamber situated next to the affected valve has to work progressively harder, either because it gets no rest in between beats (in *incompetence*); or it has to force the blood through too narrow a hole (in *stenosis*). The end result is some variety of heart failure (P27). Although there are other causes of valvular heart disease which will now be mentioned, rheumatic fever is much the commonest, and much valve trouble can be blamed on rheumatic fever even when the patient has no recollection of ever having suffered from it. The other, much rarer, causes may b syphilis, congenital valvular anomaly, heale bacterial endocarditis, atherosclerosis, an mechanical injury.

The most commonly affected valve is the mitral usually causing *mitral stenosis*, in which the opening between the left atrium and left ventricle wil sometimes only admit one finger-tip instead o three fingers as it should. In time the left atrium becomes much enlarged as it overworks to forc blood through this narrow orifice. Later still back pressure develops in the lungs causing congestion and breathlessness; and even later th right ventricle is strained as it tries to force bloo into the already congested lung. This is a classi example of the march of trouble backwards from the site of the damaged valve involving first th chamber " behind " it (the left atrium), then th territory " behind " that (the lungs), then th pulmonary arteries taking blood to the lungs, an finally the right ventricle trying to send blood t the pulmonary artery. This steady march o events is usually very slow, and can commonl take twenty years or longer from the initial attac of acute rheumatism to the severer symptoms o advanced mitral stenosis. Treatment is both medical and surgical. The heart failure is treate medically as already described. These days surgical reopening of the valve is almost commonplace, either by inserting a finger through th left auricle and breaking down the constriction or by opening up the heart and re-shaping th valve under direct vision. The latter involve the additional problem of by-passing the heart b the use of some sort of external pump and pose additional problems, even though from othe points of view it is obviously more convenient As always with major surgical procedures much o the problem is in selecting the patients who wil benefit from the operation and in whom it i feasible. Quite often there are other valve involved, mainly the aortic or tricuspid or both and the hydrostatic or " plumbing " problems ca be extremely complex. With luck, however combined with good judgement and good surgery the lives of incapacitated patients can be transformed by mitral, and other valvular, surgery The *aortic valve* is stenosed or narrowed by othe degenerative processes besides rheumatism. *Tricuspid stenosis* is nearly always rheumatic in origin

Coronary Heart Disease. This is the term use whenever the blood supply to the heart muscl (through the coronary arteries) is reduced to suc an extent that the heart muscle suffers from a lac of supplies. It has a number of causes, but th only really common one is partial obstruction o the coronary arteries by a condition known a *atheroma* or *atherosclerosis*, and sometimes inaccurately called *arteriosclerosis*. This arterial diseas is described later (P30). It takes the form o swellings or lumps on the lining of the arter which, if they become large enough to interfer seriously with the flow of blood, produce a bloo starvation or *ischaemia* of the tissue being supplied. Obviously, the smaller the artery, th more easily will a lump of given size impede th flow. Equally obviously, the greater the deman for blood, as in exercise, the more blood " starvation " there will be. There are two degrees o coronary artery disease: one in which the bloo flow is reduced to the point where the increase demands of hard work cannot be met, and thi results in *angina pectoris* due to *coronary insufficiency*: the other is when the coronary arter becomes completely blocked, preventing the flo of blood altogether, usually by a *thrombus* or clo of blood, and this is *coronary thrombosis*.

Angina Pectoris. Whenever activity is increased in any muscle, the demands for oxyge and nutriments from the blood-stream increas and as these are used up there is an increase production of waste products known as metabolites, To meet these demands for a greate supply and a more efficient waste-disposal, th blood flow through the exercising muscle mus always be increased. If sufficient increase doe

occur, not only will there be a shortage of
plies, but there will also be a pile-up of meta-
tes in the muscle which cannot be carried away.
s mainly because of these latter that pain is
sed in ischæmic, or blood-starved muscle, and
n is one of the chief symptoms when heart
scle becomes ischæmic. One important
hanism for increasing blood flow normally to
rcising muscle is by automatically dilating the
sels concerned. Diseased vessels, such as
onary arteries when they are affected by athe-
a, are not so easily dilated, although certain
gs which are powerful dilators of arterioles can
omplish a great deal, albeit temporarily. The
sures taken to relieve the pain and blood-
vation of angina are two-fold. The patient
reduce the demands of the heart by a few
utes' rest, and a drug (usually nitroglycerin)
be taken to dilate the coronary vessels of
ply. Another obvious long-term way to
ice demands is for the overweight patient to
less, and reduce the load of extra body weight
his circulation. It is very frustrating, to say
least, that such an incapacitating and often
al condition should be caused by the narrowing
blockage of only two or three inches of narrow
ng about one-eighth of an inch wide. One
ious form of treatment in theory would be
gical replacement of the piping (many larger
ries than these in other parts of the body are
monly replaced already); or surgical removal
he obstruction inside it. It is very likely that
geons will one day overcome the technical
culties involved.

eart Attack or *Coronary Thrombosis.* It
uld readily be understood from the above
ription that heart attacks will vary in their
erity according to the amount of heart muscle
rived of blood; and this in turn will depend
where in the coronary artery the obstruction
urs. Most usually it is the left ventricular
cle which is cut off from supplies and dies,
er in part or in all of its thickness. Since it is
left ventricle which does most of the work of
nping blood to the body, serious heart failure
7) is to be expected. If too much muscle is
d, the heart will simply stop, and the patient
suddenly die. It is much more usual, however,
enough muscle to be left for survival, albeit
a greatly reduced cardiac efficiency. A heart
ck is usually accompanied by severe pain,
lar to the pain of angina but more severe, and
lieved by rest or by the patient's usual drugs.
occasionally the event occurs apparently
out pain, or with so little that it is ignored.
se so-called "silent" coronary attacks can
e diagnosis extremely difficult. Since the
or depends very considerably with heart
cks on an exact, spontaneous description of
ptoms for his diagnosis, no description will be
n here. There are many over-anxious people
will read these words and could be misled
an unspontaneous description of their own
ptoms, and this could make the task of treat-
them such a problem that they could even
mis-diagnosed as a result. If you have the
lest worry that your chest pain is due to your
t, take your anxiety to your doctor without
y. He will almost certainly be able to re-
re you; and if it happens to be your heart
all, you will have taken the first sensible
towards proper treatment. Dangerous as
t attacks are, they are by no means the death
ant that many lay people think, any more
cancer is. The treatment for a true heart
ck is urgent and prolonged. Patients must
complete rest and their pain relieved quickly.
area of heart muscle they have lost must be
ved to heal with a good, firm scar, and this
ake three months of rest often in hospital.

ood-pressure. The blood is normally under
pressure in the arterial system, since it is
which forces it into all the tissues of the body.
therefore no more meaningful to say you have
od-pressure" than to say you have a tem-
ure. You would be very badly off without.
d-pressure which is too high, however, can
rise to problems, though not always. It is another of those conditions like angina and cancer, which engender much anxiety among people even when they do not suffer from them. For this reason doctors are often unwilling to disclose a patient's blood-pressure and because of this they unjustifiably earn a reputation for unreasonable secrecy. They are themselves to blame for the general public anxiety as the following true story shows. Twenty years ago a lady in her fifties wished to accompany her husband to a post abroad which was to last four years. All arrangements had been made—the husband resigned his previous job, sold the house, etc.—when it was discovered at a routine medical examination that she had a high blood-pressure, and she was very solemnly advised by the rather elderly doctor not to go. There was great consternation and emotional upheaval, not least because of the inconvenience involved. Eventually she was allowed to go at her own risk. The husband's job lasted eight years instead of four, during which the lady was in no way inconvenienced by her blood-pressure; except that she worried interminably about it. On returning home to retire she began to think she had angina, and elaborate hospital investigation revealed that, as might be expected, her arteries were not as young as they used to be. She was undoubtedly suffering from mild angina, but not as badly as she thought. The opportunity then arose, in her late sixties, to go abroad yet again, and this she did, living a quite strenuous life, and one which she enjoyed. At the time of writing she has returned home, and, twenty years later, at the age of seventy three is running a home very actively, still with very little inconvenience from her blood-pressure. There is no doubt that it has been very high all this time, and it is also certain that she will die one day, although it may well not be of her blood-pressure. How much better it would have been for her not to have been told it was high twenty years ago and to have avoided all these years of anxiety. It is not being suggested here that high blood-pressure is a trivial condition, but that it is for doctors to worry about rather than patients! If you ever find out your own blood-pressure, never try to work out for yourself what the figures mean. It is much too complicated. Finally, it should be mentioned that high blood-pressure may occasionally be associated with, or "secondary to," certain kidney diseases (*nephritis*) including a strange condition known as *toxaemia of pregnancy*, which lasts only as long as the pregnancy, provided great care is taken. Most high blood-pressure is, however, "primary", and without any known association or cause.

Low Blood-pressure. Some people seem normally to have surprisingly low blood-pressure all the time. There is nothing whatever wrong with this; indeed it may even be beneficial. At least they are unlikely ever to suffer the effects of high blood-pressure. The sudden low blood-pressure of circulatory failure or shock (**P27**) is another matter and must be urgently treated.

Irregularities of the Heart-beat. How quickly or how slowly the heart beats is largely under the control of the cardiac centre in the brain and the level of certain hormones in the blood. The *regularity* of the beat, however, is controlled by the so-called pace-maker in the wall of the right atrium, and by the way impulses from the pace-maker travel through specialised conducting heart cells (the bundle of His and its branches) to the ventricles. When any part of this elaborate mechanism is upset, either by altering the biochemical or electrical conditions of these specialised tissues, or by killing some of them off by deprivation of blood supply in the course of a heart attack, disordered rhythm can result. Increase (*tachycardia*) or decrease (*bradycardia*) in rate is nearly always a normal response to exercise, or anxiety. Very occasional irregularity, such as the mis-timing of an occasional beat is also quite normal in some people, although many are alarmed by it. Persistent irregularity, however, is abnormal. Its true nature can usually be elucidated by making an electrical record of the heart-beat—an electro-cardiogram. The commonest causes are varieties of coronary artery diseases or rheumatic heart disease.

Pericarditis. The heart beats inside a bag or sac. At every beat its outer surface slides against the lining of the sac, lubricated by a small amount of fluid. This is the pericardial sac, the *pericardium* being strictly the lubricated membrane which lines the sac and which also covers the outer surface of the heart. Sometimes inflammation occurs—*pericarditis*—and the sliding surfaces become roughened and even separated by a fluid effusion. Very occasionally, so much fluid accumulates that the heart's action is seriously impeded. Pericarditis may be due to infection or to rheumatic fever, and it usually overlies the area of damaged muscle after a heart attack. This illustrates something which people rarely appreciate—that inflammation is not by any means always due to infection by bacteria. The last two varieties of pericarditis are quite free from germs (sterile).

Myocarditis. A term loosely applied to disorders affecting the heart muscle. There are lots of very rare causes. The really common ones are due to acute or chronic rheumatic causes or to coronary artery disease, both of which are described above.

Endocarditis or inflammation of the lining of the heart is a term loosely applied to any disorder of the valves or heart lining. All varieties of rheumatic valvular disease (**P28**) are included. Bacterial endocarditis in its several forms usually involves valves already damaged by rheumatic disease. It is a complication which is still much to be feared, though somewhat less so now that antibiotic drugs are available.

Atheroma or Atherosclerosis. This is the condition referred to above in which lumps arise on the lining of arterial blood-vessels. Although it is therefore a disease of the arteries, its importance lies in the way blood flow is held up, either by the lumps themselves, or by thrombosis ultimately blocking the narrowed portion of the pipework. The effects on the body are therefore those of depriving the tissues of blood. It is an astonishing fact that in England and America, more people die of the consequences of atheroma than of any other single disease, including all forms of cancer put together. Furthermore, cancer is mainly a disease of old age, whereas many of the effects of atheroma on men occur in early middle age. If narrowing of the artery is going to do significant harm it is easy to see that it will be of more consequence in those parts of the body where small-bore vessels are supplying tissues whose functions are necessary for life. Exactly such a situation exists in the heart and in the brain. An additional factor is that the arrangement of the blood supply in these tissues is such that any particular area has only one vessel leading to it. This is unusual among the tissues generally, where several alternative, or "collateral" vessels usually supply an area, and where others can take over if one becomes obstructed. We have, therefore, a situation in which perhaps the most important tissues —the heart and the brain—run the greatest risk of deprivation, and this leads to angina and coronary thrombosis on the one hand, and cerebral thrombosis and hæmorrhage ("stroke illness") on the other, accounting jointly for about one death in every five. In addition, the effects of atheromatous narrowing are often felt in the legs, where the blood supply to the muscles is inadequate for exercise, leading to intermittent pain comparable with that in the heart in similar circumstances. This is called *intermittent claudication*, or intermittent closing of the leg arteries. In its most severe forms, it leads to the need for amputation, although in most cases early treatment can avoid this. It is small wonder that there is intensive research into the causes of atheroma, as with cancer, but it is probably true to say that we still know rather more about cancer. A lot of attention has been given to the amounts of certain fats in the circulating blood, particularly cholesterol. This fat is found in larger amounts in the blood of sufferers from atheroma, and is also found in the arterial lumps themselves. Efforts have therefore been made to reduce blood cholesterol by modifications of the diet, but it has been extremely difficult to prove that this has done any good. Many other factors are known to contribute to atheroma, and hence to heart attacks and strokes, some of which can be reduced and others not. Such factors are age, obesity, high blood-pressure, and smoking cigarettes. People who lead an active life, like bus conductors, seem to have less trouble than others who are less active, like bus drivers. Sudden severe exercise, however, is bad if you are not used to it. It is better, and life saving, to take regular, moderate exercise. Women have less atheroma than men, until the menopause when they begin to catch up, so that hormones have something to do with it. Serious starvation, such as occurred in the German-occupied territories of Holland and Scandinavia and in the concentration camps conferred one benefit—a freedom from atheroma, but obviously we cannot all starve, and the puzzle remains. Like many of the more important outstanding medical puzzles, there is no single factor responsible, and this is what makes it difficult to solve.

Aortic Disease. The aorta, the main artery of the body, running from the left ventricle down through the chest and abdomen, also suffers from atheroma, but is too wide (about an inch across) to become obstructed. However, weaknesses occur in the thickness of its wall, sometimes due to syphilis but nowadays much more usually due to atheroma, which results in a ballooning out of a part of the vessel, rather like you sometimes see in an old bicycle inner tube. In days gone by these *aneurysms*, as the dilations are called, reached an enormous size, and would wear away the breastbone and ribs, to appear as large pulsating masses on the chest. Now that advanced syphilis is less common, atheromatous aneurysm, with a predilection for the abdominal aorta, is the one most commonly seen; and these days it is treated by replacement of the diseased portion of vessel. *Dissecting aneurysms* of the aorta are another variety in which the blood, under high pressure, somehow finds its way in between the layers of the aortic wall and then suddenly rips up and down the whole length of the vessel, separating (or dissecting) one layer from another in its path. Sometimes it tracks back towards the heart and suddenly fills the pericardium with blood to stop the heart's action altogether.

Embolism. This term refers to any foreign object travelling in the circulation and becoming impacted when it reaches a vessel too small for it to pass through. It may be a thrombus (**P31**) a collection of cancer cells, a group of bacteria, a chunk of infected pus from an abcess, a collection of fat droplets or even a bubble of air. If it originates in a vein it travels to the right heart and to the lungs. If it comes from the left heart or an artery, it will impact in any part of the arterial tree. Reasonably enough an arterial embolus will commonly end up in those parts of the body with the richest blood supply, like the brain, the kidneys, the liver or the bone marrow. A thrombotic embolus will cause death of the tissue in the area previously supplied by the blocked vessel, a condition known as *infarction*. Perhaps the commonest source of thrombotic embolism is the lining of the heart chambers where a thrombus has occurred at the site of muscle damaged by a heart attack. Massive pulmonary (lung) embolism is usually the result of thrombosis of the leg veins in people kept immobile following surgery or childbirth. That is why postoperative patients are got out of bed for a while as soon as the first day after the operation. The cells of a cancer embolus usually die; but if they survive, a new cancer deposit begins to grow where the embolus impacts, and this is one of the ways cancer may spread. An infected embolus may infect the vessel wall when it impacts, producing a weakness

ch may give way. Air embolism, if enough
luble gas enters the circulation, can kill by
ing so much froth in the heart chambers as
npede the normal pumping action. If bubbles
the lungs and enter the brain, all sorts of
rological disorders like scores of tiny strokes
. The same sort of thing happens all over
body in the "*bends*" or "*caisson*" *disease*,
hich the blood literally boils. It is due to a
rapid return to normal pressure from regions
gh pressure at great depths or from pressurised
nbers. Fat embolism sometimes occurs after
tures due to marrow fat entering damaged
s and being carried away to the lungs.

hrombosis. This is not quite the same as
ing. It is the mass which arises when plate-
adhere to the lining of blood-vessels or heart
nbers. Blood clot accumulates among layers
eposited platelets and the thrombus therefore
structure, unlike pure blood clot. Throm-
s usually occurs when the lining of the vessel
hamber is damaged by atheroma or inflam-
ion, or when the circulation becomes very
nant. One danger is that it will become dis-
ed and travel as an embolus during the first
or ten days of its existence. After this time
usually firmly incorporated into the vessel
s by cells which migrate into it from the sur-
ding tissue. The other danger is, of course,
the tissue previously supplied by the blocked
el will die before a collateral circulation can be
olished. As previously explained, this is
d infarction. All the technical terms in this
on are used elsewhere and can be looked up.

uerger's Disease or *thromboangiitis obliterans*.
is an inflammation of the arterial wall which
to blockage by thrombosis. The leg arteries
mparatively young men are most commonly
ted, leading to amputation in some cases.
e lung cancer, coronary heart disease, and
chitis, which are known to be associated with
ing, Buerger's disease is only thought to be.
e is a horrible tale of a young man who had
all his four limbs one after another, sitting
he hospital steps begging passers-by to light
garette for him.

ynaud's Disease. This is a strange condition
hich the finger tips and in severe cases all the
rs or the whole hand respond in an exag-
ed way to cold. The vessels supplying the
are constricted and the fingers go white as
lood drains from them. Then the capillaries
e and become distended and filled with blood.
wing to stagnation it is venous and blue, and
ngers are therefore blue. Now we have all
ienced this in very cold weather, but sufferers
Reynaud's disease, nearly always women,
nd even to very slight cold, like putting their
s into cold water. Even emotional stress
tart the process off. In very severe cases
ngers will be so deprived of blood for so long,
sores will develop and fingers can even be
but this is very rare, and can be avoided by
eration to cut the nerves which supply the
ar muscle of the vessels concerned. In most
it is sufficient to avoid getting the hands

stbite. Strictly speaking, this is literally a
ng of the tissues. Although their freezing
might be expected to be close to that of
, it usually only occurs at temperatures
−13° C (8° F). The patient may feel a
ng feeling at first, and feel an area of firmer,
kin on the cheeks, nose, ears, fingers, or toes.
se parts are numb with cold, the onset of
ite may not be felt, and will often only be
d by others. In countries where extreme
s prevalent, it is usual for complete strangers
p each other in the street and point it out
they see it. It is important not to rub the
ed part, but contrary to popular belief it

must be warmed as *rapidly* as possible. Fingers should be immersed in water as hot as the normal hand can bear (110° F). Many First Aid books still quite wrongly teach that return to warmth must be gradual.

DISEASES OF THE RESPIRATORY SYSTEM

INTRODUCTION.

The respiratory system is concerned with taking into the body the oxygen which is necessary to life and getting rid of the carbon dioxide which is a waste product. It begins at the nose, which is intended (although not always used, since there are many mouth-breathers) as a filter and air-conditioner. The hairs in the nose keep—or are intended to keep—dust particles from the throat, and its sticky lining, warmed by the blood-vessels in which it is so rich, has the double function of removing the finer dust and germs and warming the air taken in.

After this process, the air passes down from the back of the nose to the space behind the mouth and then down the windpipe or trachea into the lungs. On the way it goes through the larynx or voice-box (above the trachea), which makes speech possible with its mechanism of vocal cords; the vocal cords separate during breathing in order to let the air through. Lastly, in the chest the windpipe divides to right and left and goes into the lungs; these main divisions are the bronchi, and within the lungs they subdivide, rather like the arterial system, into smaller and smaller tubes, known as bronchioles, which end up by entering the air-spaces of the lung tissue. There, in the thin, spongy spaces lined with blood-vessels, the breathed-in air gives up its oxygen to the blood.

The two lungs, right and left, lie within the chest attached to the bronchial tubes and the large blood-vessels. These are their "roots." They are, like the heart, covered with a double layer of thin, plastic-like material, the pleura (the part which is affected in pleurisy), and they contract and expand with the movements of breathing. But breathing is not carried out by the lungs themselves—it happens when the muscles between the ribs draw the ribs up and so expand the space within the chest that air is sucked in. Normally the pressure within the chest is less than that of the air outside, so that if the chest is punctured the lung collapses. This is important both in chest surgery and in certain conditions where, as we shall see later, it is desirable to collapse the lung in order to rest it. The left lung is divided into two portions or lobes, the right into three.

When one thinks of the nose, certainly if one thinks of it in medical terms, the first disease that comes to mind is the *common cold*, about which we know so much and yet so little. Colds are a virus infection which, even if trivial, cause considerable discomfort and much wasted time; but research seems to show that a great deal depends upon the type of person in whom the virus arrives. Thus people sent out in thin sports clothes to run for long distances in the rain and then made to rest in their wet apparel showed no special liability to catch cold, but it seems possible that sudden changes of temperature may have some effect. For example, in America, where central heating in some areas is very hot and the weather outside may be very cold, nose infections are common.

Even more perplexing, however, is the fact that, like the judges we read of in the daily papers, we often have to ask: "What *is* a cold?" Everyone who has a running nose or even a temperature is not necessarily suffering from coryza, the scientific name for the common cold; they may have *allergic rhinitis*, similar to hay fever, which has no connection at all with infection. In this case the symptoms are produced by dust, pollen, or some other material to which the person is sensitive. Nasal discharge and temperature may also be brought about by *sinusitis*—that is to say, an infection of the spaces within the bone of the skull which communicate by small openings with the inside of the nose. These are the frontal sinuses just behind the eyebrows, the maxillary sinuses below the eyes, the ethmoid sinuses in the corner of the eyes on either side of the nose, and the more deep-seated sphenoid sinus right at the back of the nose. When these cavities are infected pus forms and naturally discharges into the nose, but if the lining of the nose swells up (as it does, for example, in a hot room) the openings into the nose may be blocked, the pus accumulates, and there is severe pain over the site of the sinus. Sinusitis may respond to the sulpha drugs or to antibiotics, but it is sometimes necessary to make a new opening into the nose and wash them out or to operate.

Whenever anything goes wrong with the nose, whether it be a virus infection, an allergic irritation, or discharge from the sinuses, there is always a secondary invasion by germs which are the result rather than the cause of the trouble; the thick pus which comes from the nose in the later stages of a " cold " is largely due to them. There are no injections or inoculations against colds, but conceivably *some* of the many available may prevent colds getting worse by dealing with the secondary invaders; they certainly do not deal with the original cause, the virus. Capsules taken by mouth are, there is every reason to think, completely valueless, and, so far, the treatment of a cold is simply the treatment of the symptoms: aspirin relieves pain when it exists, it reduces the fever, and it does nothing else. Nor has whisky any special effect, although it is so often prescribed as a cure, but it probably has some effect on devotees in making a cold more bearable.

Hay Fever is an allergic condition due to hypersensitiveness to the pollens of certain grasses. Its symptoms have already been described so far as the nose is concerned (see allergic rhinitis), but there may be other signs of allergy, such as redness of the eyes and itching of the skin. Hay fever is helped by desensitisation with increasing strengths of the substance responsible: since cases occur mainly in May or June, the course of injections should be given early in the year. It usually has to be repeated each year. An alternative is the use of one of the antihistamine drugs, which seem to afford relief—but not cure—to many people.

Epistaxis. Another condition which is not really a disease in itself but may be a symptom of one is *epistaxis* or nose-bleeding. Bleeding may be caused by injury, by nose-picking in children (who frequently put beads or other small objects in their noses), by polypi (similar to varicose veins), and by a number of general illnesses, such as high blood-pressure, blood diseases, and fevers. It sometimes occurs in women during their periods and in people at high altitudes, flying or mountaineering. Usually no special treatment is necessary, but if the bleeding becomes troublesome a doctor will probably pack the nostrils with gauze soaked in adrenalin. In ordinary cases cold compresses and lying down should suffice.

Tonsils and Adenoids. The tonsils, one on each side, lie at the back of the throat, and are easily visible when the mouth is opened wide; the adenoids cannot be seen, since they lie at the back of the throat behind the nose. *Acute tonsilitis* is usually, but not always, caused by the streptococcus, and it results in sore throat, high fever, and difficulty in swallowing. But, as we saw elsewhere, its main danger is that it may become chronic and cause damage to the heart and other organs. Tonsilitis responds to antibiotics and the sulpha drugs. Adenoids, when they become infected, swell to an extent which may cause difficulty in breathing and block the air passage between the nose and throat—the Eustachian tube—leading to ear infection or loss of hearing. This produces a typical facial expression: the child looks dull and listless, breathes through its mouth, which is therefore constantly open, and talks in the manner of someone with
cold. It must be remembered that this occu
only in severe cases, that most children have so
trouble with their tonsils and adenoids in ear
life, and that after the tenth year the tissues te
to shrink, so that difficulties after that time a
much less frequent. The realisation that s
called enlargement of the tonsils and adenoids
so often simply a normal stage of developme
has led many doctors to believe that they a
much too frequently removed.

Chronic Bronchitis is typically a disease of th
old, or at any rate of those in later life. It
something which is always " there," but becom
worse in winter, in cities where there are fogs, i
children with adenoids, and in older people wh
work in occupations where they are exposed
dust. Chronic bronchitis develops gradually
the result of many previous attacks and, since th
lung tissues sooner or later become involved, a
no longer elastic, and show *emphysema* or d
generation of the spongy substances which abso
oxygen, it would be wrong to pretend that the
is any cure. People with chronic bronchitis ma
be helped by certain drugs, but they are not cure
when irreversible changes have occurred. In th
case, a large part will be played by cough mixture
and it is important to realise that these are of tw
types: sedative and expectorant. A sedati
mixture is intended to stop irritation which
useless, and does not perform the function of
cough in bringing up secretion. For instanc
in laryngitis there is an irritating cough whic
is simply caused by stimulation of the tissu
when there is no secretion to get rid of, and in th
case it would be reasonable to give medicine whic
stops the cough, but when secretion is present
has to be removed, and here one has to take som
drug which will make one cough more effectivel
A stimulant mixture is one designed to lique
the sputum and help to get it out of the syste
(Incidentally, one of the best—even in these day
of " wonder drugs "—is the solution of commo
salt used in Brompton Chest Hospital.) The
are numerous good means of suppressing cough
but probably very few good expectorants, a
though each patient swears by his own speci
mixture; and he may be right.

If lung or bronchial disease has been present fo
some time there may develop certain degenerati
changes, such as *bronchiectasis* or *emphysem*
In bronchiectasis the bronchial tubes becom
dilated, first of all in a single lobe of one lung an
then elsewhere, with the result that the stagnan
and infected secretions are retained very large
within the chest, damage further the bronchi
linings and the lung tissue, and end up in a viciou
circle: pus accumulating, bronchitis, more pu
and more bronchitis. All the signs of chron
bronchitis are present, but what is typical is th
large amounts of foul-smelling pus which a
brought up. Bronchiectasis is a serious disease
but the antibiotics and the sulpha drugs hav
improved the outlook, and lung surgery (lobectom
or removal of a lobe and pneumothorax or co
lapsing of the lung) is also used in suitable case
In emphysema the deterioration takes place
the lung tissue, and if you recall that the lung
the place where the oxygen of the air taken
meets the blood within the internal surfaces, yo
will see that the amount of surface available is
great importance. In fact, the normal lun
internal surfaces are about the size—if they we
spread out—of a tennis-court. But in emphy
sema the elastic tissue between the cells begins
give way, the surface available for oxygenisi
becomes smaller, and, as the walls of the cel
collapse, so do the number of capillaries.
order to get the same amount of oxygen into th
blood, the heart has to work much harder.
emphysema, like most chronic lung disease, lea
to heart trouble—the heart has to work harde
to get the blood through.

Cystic Fibrosis is an inborn disease which affec
chiefly the lungs and the digestive system. It
sometimes called *Fibrocystic disease of the Pa*
creas, and sometimes " Muscoviscidosis " Unt
it was medically recognised twenty-five years ag

lren affected usually died from pneumonia in
irst year of life. This, of course, was before
oiotics were available for the treatment of in-
ons. Today, cystic fibrosis is known to be the
nonest genetically determined disorder affect-
children in Britain. One child in 2,000
ves one of the abnormal genes from each
nt. Such a child therefore has a double dose
e harmful gene, and will have the disease from
. One person in 25 of the general population
es only one of these abnormal genes, and such
ndividual will not have the disease, but will
carrier of the abnormal gene. If such a
ingly normal carrier marries another carrier,
is a one in four chance of each of their child-
being affected. The children, therefore, who
ally develop cystic fibrosis, have inherited
disease *equally* from both parents, who are
ers, but are themselves unaffected by the
se. Although much has been learned about
c fibrosis in the past twenty-five years, there
in many unsolved problems, and we still
ot define precisely the biochemical fault which
es it. The prospects for survival into reason-
healthy adult life are steadily improving, but
depend upon early diagnosis and careful
agement through childhood. In cystic
sis most of the damage is caused by the exces-
viscidity, or stickiness, of the mucus which is
uced in the breathing tubes as a lubricant, and
in the ducts of the pancreatic gland which
ides enzymes to help digestion. Being thick
sticky, instead of thin and slimy as in the
al, this mucus tends to block the passages
ad of keeping them clear. The pancreatic
are permanently destroyed. The gland
ot secrete pancreatic enzymes, and the food,
ially protein and fat, is not properly ab-
d. This deficiency can be compensated
well by giving pancreatic extract by mouth
every meal, and by dietary care.

e major clinical problem is in the lungs. The
passages normally have a thin coating of
s which is propelled steadily upwards, and is
letely renewed in less than one hour. It
s more suddenly on coughing. In cystic
is this upward movement is slowed down and
rupted. There is difficulty in keeping the
ges clear, especially when infection with
ria or viruses greatly increases the amount
ucus. This results in intermittent blocking
e air passages, difficulty in breathing, in-
lete use of the lungs, and persistent local
ets of infection. If such infectious processes
ot controlled, areas of lung will be destroyed,
ic infection will persist, and multiple lung
es will develop. These predispose to fur-
nfection, interfering with the natural develop-
of the lung—a process not normally complete
halfway through childhood—thus adding to
espiratory problems which the child will face
er life. Unless a correct diagnosis is made,
proper treatment instituted before the first
s lung infection has occurred, the resulting
damage may well be permanent. The Cystic
sis Research Foundation Trust of Stuart
e, 1 Tudor Street, London, E.C.4., was
ed in 1964 to raise funds to finance research,
o help and advise parents with everyday
ems in caring for these children.

LUNG SURGERY.

e heart surgery, lung surgery has greatly
oped in recent years and is used in four main
ories of disease: infections, cysts, tumours,
n wounds. Infection is mainly due to
hiectasis and tuberculosis—although other
ions may arise; cysts are not very common,
eed not necessarily give trouble unless they
e infected; tumours, if malignant, obviously
o be removed; and how a wound is treated
ds on its severity. Generally speaking, the
tions performed are: (1) drainage; (2) re-
of part of the lung; or (3) collapse of the
Drainage is carried out when—as in the
f an abscess or infected cyst—there is an
containing pus, and the purpose of the
lure is to let the pus out. *Removal of part*
lung, or in some cases a whole lung, is
l out where there exists bronchiectasis or tuberculosis or cancer limited to a particular area; clearly such an operation is serious, but the results today are good, although, of course, this depends in part upon the initial condition from which the patient was suffering. *Lung collapse* is carried out when infection is present, but it is thought that recovery might occur after a "rest"; for collapse means that the affected lung is put out of action and is not used for breathing. Collapse is carried out in various ways. In *pneumothorax* air is injected into the chest by a simple procedure, causing collapse; in *pneumoperitoneum* air is injected into the abdomen, with the same result, since by pushing up the diaphragm it causes collapse; in *phrenic nerve crush* the nerve supplying the diaphragm is crushed under a local anæsthetic where it passes through the neck. In more serious cases *thoracoplasty*—the removal of all or portions of the upper ribs—may be performed under a general anæsthetic.

Lung Cancer is one of the most obvious reasons for surgery, and as most people know by now, it has been established that there is some connection between lung cancer and tobacco-smoking. The facts, as known, are complicated, but some of the more important are these:

> (*a*) Between the ages of fifty and sixty-four those who smoke more than twenty cigarettes a day have a death-rate more than twice as high as non-smokers (although not necessarily from lung cancer).
>
> (*b*) Five moderate smokers die of lung cancer to every one non-smoker and fifteen or sixteen heavy smokers.
>
> (*c*) It seems certain that other factors are important. For example, the death-rate from lung cancer is very much higher in cities than in the country, the incidence is higher amongst cigarette smokers than amongst pipe or cigar smokers. Diesel fumes and smog probably play a quite important part, and the considerable increase in cancer (which is, however, commoner in men than in women) runs parallel both with increased cigarette smoking and increased fumes from car exhausts—particularly Diesel fumes.
>
> (*d*) As in the case of coronary thrombosis, we can see that it is not easy to analyse out the real cause of the trouble in lung cancer. We have to consider the soil—the person affected Is there, perhaps, something within the individual which predisposes him to cancer, and that smoking merely determines *where* he will get it? We do not know, but it is a possibility.

There are few early symptoms and the condition is usually discovered by accident at a mass X-ray centre. Pain in the chest, loss of weight, and coughing blood are late symptoms. The only treatment, if the disease is found in time, is removal of the whole or part of the affected lung.

Asthma is a chest disease which we will discuss at this point, since it will serve to introduce the general problem of *allergy*, although other allergic diseases will be mentioned elsewhere according to the part of the body affected. The causes of asthma are mainly three: allergy, chronic bronchitis, and emotional disturbances, although in varying degrees they go together in any one person; there is a likelihood that allergy and emotional sensitivity are related and that in cases with bronchitis the patient may be allergic to his own germs. People may be allergic to all sorts of things: to pollens, feathers, and numerous particles present in the form of dust in any house or any city street; to foods such as shellfish, to penicillin, to injections given them at the doctor's, and a case was even reported from America in which a man got a divorce because he was allergic to his wife and developed a skin-rash whenever she embraced him! Asthma is simply one form of allergy, in this case affecting the bronchi, which go into spasm when the person comes into contact with the stuff to which he is sensitive. But allergy can affect the nose and eyes, as in hay fever, the skin, as in dermatitis, the joints, and the bowels. In an asthma attack the patient finds it more and more difficult to breathe, his chest is widely expanded, and the main trouble is in breathing out. Such attacks often come on at night, and may occur almost daily, or as infrequently as one every few months. Although asthma is an allergic disease, the attacks are very often set off by emotional crises of rage or resentment. In some cases the emotional element is even more obvious, as when a woman allergic to roses developed an attack when shown into a room in which there was a bunch of roses on the table, which were, in fact, artificial! The immediate treatment for an attack is to give something which will relax the tubes, usually adrenalin injections or ephedrene taken as tablets by mouth. The long-term treatment is directed towards finding the substance to which the patient is sensitive and by a course of injections attempting to desensitise him. Unfortunately this does not always work, but in some cases antihistamine drugs may help. However, the trouble with asthma, as with other chronic lung diseases, is that when it has existed for some time changes occur which are irreversible, such as chronic bronchitis or emphysema. When this stage is reached the best that can be done (and it is a great deal) is nevertheless palliation.

Allergy is to be understood as a perversion of the normal body reactions towards certain substances—mainly, but not always, proteins. Such substances act, just as do the toxins of germs, as antigens: that is to say they cause the formation of counter-substances designed to neutralise their influence, and these counter-substances are known as antibodies. Normally, this takes place successfully within the blood, and when a second dose of the foreign protein gets into the body its effect is neutralised. But when, due to some unknown cause, this does not happen, the antigen, or foreign substance, gets into the body cells and causes the liberation of a poisonous chemical known as histamine. It is this which causes the symptoms in allergic diseases, and which is sometimes countered by the antihistamine drugs. In extreme and rather rare cases a person with this sort of disability may get an injection, and if there has not been sufficient time for antibodies to form, a second injection of a completely harmless stuff, such as a serum, may lead to sudden death. This is known as *anaphylactic shock.*

Allergy, then, is due to an inability to produce antibodies, and this, in turn, is the result of: (*a*) heredity—for such diseases run in families; (*b*) to the person's physical condition at the time; and (*c*) to emotional causes which can interfere with antibody formation.

DISEASES OF THE DIGESTIVE TRACT

INTRODUCTION.

The digestive tract begins at the mouth and ends at the rectum, where the waste products are excreted. The food taken in at the mouth is moistened with saliva secreted by the salivary glands, of which the largest are the parotid glands—they are the ones which become swollen in mumps. The smaller glands are the submaxillary (under the jaw) and the sublingual (under the tongue). The act of chewing breaks the food down and helps to mix it with the saliva. Saliva contains an enzyme called ptyalin, which starts the digestion of starchy foods, and the food thus reduced to a pulp passes down the œsophagus, a tube about 2 ft. long leading through the chest down to the stomach, where the main part of digestion begins. The gastric juice, as everyone knows, contains hydrochloric acid, which in concentrated form is a dangerous caustic and will burn holes in carpets or anything else if allowed to—as certain advertisers at one time were not slow to point out. Advertisements used to show the dreadful effect of the acid on a carpet, and invite the gullible to consider what would be the effect on the much more delicate stomach; the effect could, of course, be neutralised by "Biffo" or whatever was the name of the stomach powder. This, needless to say, is a piece of nonsense; hydrochloric acid in the stomach is important for
digestion (although some seem to manage witho
it), and it exists in such a diluted state that
could not burn a hole in a piece of tissue pap
However, the details of this will be discuss
later when we are talking about ulcers. Suff
it to say that the acid is intended to be there, a
causes harm only when something else has go
wrong with the stomach.

Also in the juices secreted by glands in t
stomach lining are the substances known
enzymes, which are found not only there but pl
a large part in all body processes. By bringi
about chemical changes they make life possib
and we have already mentioned one, ptyali
which functions in the saliva to break down star
into sugar. The word enzyme is derived from tw
Greek words meaning "in yeast," because the fi
enzyme known to Man was the one in yeast whi
breaks down starchy foods into sugar and, give
time, as brewers and some less-respectable ge
tlemen know, into alcohol. In the stomach t
main enzymes are pepsin, which changes insolub
proteins in food into peptones, in which fo
absorption through mucous membranes is possib
and rennin (essence of rennet obtained from t
cow's stomach is the stuff used to make curds a
whey). In the small intestine the food com
under the influence of the alkaline juices, secret
partly by the intestine itself and partly by t
pancreas; the most important enzymes here a
trypsin, which breaks down proteins, amylas
which continues the work of breaking dow
starches, and lipase, which breaks down fats.

The end result is that by the time it reaches t
end of the small intestine all the food we ha
eaten, however varied, is broken down into ve
simple chemicals: the proteins into substan
known as amino-acids, the fats into glycerine a
fatty acids, and the starches and sugars in
glucose. The fact that glucose does not have
be digested, and that carbohydrates generally a
the fuel of the body give rise to the quaint noti
that glucose makes you energetic (hence all t
tablets, drinks, and so on containing gluco
which, from the remarks made about them
advertisers, one might suppose to be the elixir
life). Unfortunately, although glucose is use
as a temporary food in those who cannot—
after an operation—absorb anything else, the
are very few people who need any extra. Mo
of us don't need more energy; we need mo
brains to make use of what energy we have.
spoonful of glucose is no better and no worse th
a couple of lumps of ordinary sugar or a slice
bread so far as giving energy is concerned, for t
simple reason that all end up in the same wa
as glucose.

After being thus broken down, the fatty ac
and glycerine enter the lymph channels pass
from the intestinal walls and so get into the blo
and thence to the areas under the skin which g
some ladies their "vital statistics" and ma
men and women their "middle-aged sprea
but the amino-acids and glucose pass through
special system of veins, the portal system, to t
liver to be stored until they are needed.

The small intestine includes the duoden
which joins the stomach at the lower end, wh
there is a sort of valve known as the pylor
The duodenum is about a foot long and c
tinues into the jejunum and ileum, which toget
are about 23 ft. long. At the end of the ileum
small intestine joins the large intestine or col
and this, at the right-hand lower corner of
abdomen, is the site of the appendix. Fina
the 5-ft.-long large intestine passes to the rect
which is only 6 in. long and leads to the an
the band of muscle which ends the digestive tra

Later on we shall deal with problems of d
and nutrition, but at present it is more c
venient to wend our way down the length of
alimentary canal and discuss the various disea
which can affect it. Little need be said about
teeth, since most people know about the princip
of dental care, although they do not always ca
them out with any degree of complete
Briefly these are: brushing the teeth at least tw
a day, but preferably after every meal; avoid
too much sweet food, and especially the kind
nauseous confections which stick to the tee
and going to the dentist every six months.

y are at this stage the only treatment is
, in which the "ballooning" part is tied
 the base. The operation is obviously a
one, but recovery is almost invariable.

ic Ulcer is a name covering two separate
ions—*gastric ulcer*, which is an ulcer in the
h, and *duodenal ulcer* in the duodenum.
mmediate cause of ulceration is that the
ve juices have, for some reason or another,
d away a part of the wall of the tract. It
s that ordinarily, although the stomach
est protein from outside, it does not digest
because there are chemicals in the lining—
known tentatively as "anti-enzymes"—which neutralise the effect of the hydrochloric acid and the enzymes. Why does this protection break down?

This is an important disease because it is so common, and perhaps we had better have some facts:

(*a*) About 10 per cent. of all adults have had at one time or another an ulcer of the stomach or duodenum.

(*b*) Nearly 90 per cent. of these ulcers clear up by purely medical attention, without surgery.

(*c*) When people say they have "an ulcer in the stomach" they usually mean an ulcer in the duodenum. Only one out of twelve ulcers are in the stomach.

(*d*) The indications for operation are, in general: (1) when the ulcer is chronic and medical treatment has failed; (2) when there is severe bleeding caused by the ulcer eating into a blood-vessel; (3) when, as sometimes happens, the ulcer forms scar tissue which contracts and obstructs the passage of food; (4) when an ulcer perforates.

A perforated ulcer is one which has eaten right through the stomach wall, and in these circumstances an emergency operation is necessary, for the stomach contents pass into the abdominal cavity, causing *peritonitis*—*i.e.*, a septic infection of the peritoneum, the delicate lining which covers the abdominal organs as the pericardium covers the heart and the pleura the lungs.

Typically, ulcer pain is in the upper abdomen, comes on about half an hour to two hours (depending upon its site) after meals, and is relieved to a greater or lesser extent by alkalis or taking more food. The medical treatment consists in dieting on easily digested foods taken "little and often" so that the stomach is never empty but never full. Alkaline powders are usually prescribed by the doctor, and sometimes muscle relaxants such as atropine are used to relieve the spasm which is the immediate cause of pain. It cannot be too strongly emphasised that symptoms such as those described above if they persist for any length of time should be referred to a doctor. Self-treatment is very risky.

Operative treatment is designed to reduce the hyperacidity which causes the trouble. The two main operations performed are *gastrojejunostomy*, in which part of the jejunum is stitched to the stomach so that the alkaline juices of the small intestine can enter the stomach and partially neutralise the excess acid, and, much more frequent nowadays, *partial gastrectomy*. In this operation the part of the stomach which contains the acid-secreting glands—the lower three-quarters—is removed, the duodenum is closed, and the remaining quarter of the stomach is stitched to the small intestine. This operation is very successful, and only about 1 per cent. of cases have any further symptoms. Finally, *vagotomy* is sometimes performed—*i.e.*, cutting of the vagus nerve, which passes down from the brain through the neck and chest to the stomach; for it is the impulses passing down this nerve which are responsible for the over-secretion of acid.

Why is peptic ulcer becoming so common? Most doctors would agree that it is one of the diseases caused by stress and the problems facing us in an age of anxiety. It is more common in industrial communities than in peasant ones and in people whose work is a source of worry—who are continually tense. There is no reason at all to suppose that irregular meals and the other dietary reasons often given have any influence in producing an ulcer, although one must, naturally, be careful about these when an ulcer is present. Duodenal ulcer is common in the fairly young and fit, stomach ulcer in the old and poorly. For some reason, although duodenal ulcers almost never become malignant, about 10 per cent. of stomach ulcers do so, even although there may have been no previous history of dyspepsia.

Cancer of the Stomach is found most frequently in men between forty-five and sixty. The pain of cancer tends to be constant rather than periodic, and there is increasing loss of weight and anæmia. Operation is necessary, but the outlook is good if the condition is discovered in time. There would be much less risk of cancer getting beyond the stage where operation can help if people with "indigestion" lasting any length of time would put themselves immediately under medical care with periodic check-ups. A curious feature of cancer of the stomach is that hydrochloric acid is completely absent.

Gastritis means inflammation of the stomach lining; it may be acute or chronic. In acute gastritis eating too much food or eating unsuitable food in a person with a sensitive stomach may lead to symptoms, but the most frequent cause is too much alcohol. The symptoms, in general, are those of a "hangover": headache, depression, loss of appetite, and, as P. G. Wodehouse puts it, "a feeling that you're going to die in about five minutes." In more severe cases there may be a raised temperature and diarrhœa. The treatment is to avoid irritating the stomach further, to eat only as much bland food as one feels inclined to, and to take some alkaline medicine—"fizzy" salts are suitable for this. Since "gastritis," strictly speaking, refers to any form of irritation of the stomach lining, it can also be applied to serious conditions, as when poisons such as strong acids or other corrosives are swallowed, intentionally or otherwise. Here we are discussing only the condition which is ordinarily understood when the word is used.

Chronic gastritis, although it may be associated with kidney, lung, heart, or blood diseases, and with diabetes, is usually the sequel to frequent attacks of acute gastritis. Here, again, the appetite is poor, there is depression and a feeling of discomfort rather than pain after taking food. Headache, flatulence, and vomiting or nausea in the morning are common features. Although one is inclined to picture the case of chronic gastritis as typically a retired colonel from India or some other tropical spot who has subsisted for years on curries and alcohol, there is no reason to suppose that curries have anything to do with it. Even alcohol can be taken in large amounts without doing any harm (except to one's pocket!) provided it is taken diluted and with meals. In fact, many elderly ladies of irreproachable character suffer from chronic gastritis, and it is well to remember that strong tea taken too frequently causes red noses more frequently than strong drink. Chronic gastritis requires special medical attention.

Nervous or Functional Dyspepsia is a term used by doctors which means, first, that the condition is basically a sign of general neurosis and, as such, needs a psychological rather than a physical approach, and secondly, that no signs of organic disease of the stomach have been found on examination. This, of course, does not make the discomfort any easier to bear from the point of view of the patient. The symptoms tend to be different from the more or less cut-and-dried ones of ulcer: for example, flatulence and nervous vomiting are frequent. *Flatulence* is a gastric neurosis due to the habit of swallowing air; for no "gas" is formed in the stomach, and all that is brought up has previously been unconsciously, swallowed. Trying to "bring it up" as many people do to the distress of those near by, only results in more air being swallowed, so the desire should be resisted. *Anorexia nervosa* is another gastric neurosis in which the patient refuses to take food or vomits it up when it has been taken. In some cases even death may result from self-imposed starvation of this type, for which psychological treatment is necessary.

The end of the stomach where it joins the duodenum is known as the pylorus, a ring of muscle which acts as a valve and allows the partially digested food to pass from the stomach only when it is ready for further digestion by the intestinal juices. In newly born babies the pylorus muscle may be too thick or it may tend to go into spasm easily, with the result that food cannot get out of the stomach and is vomited up. This is known as *pyloric stenosis*, and is quite common in babies of two or three weeks of age—three times more frequently in boys than in girls. Without treatment the continued vomiting, which is very forceful in character, would lead to death through malnutrition and lack of fluids, but fortunately treatment is relatively simple.
some cases, injections of a drug to relax
spasm is sufficient, but more often an operatio
necessary. A small incision is made under
anæsthetic, and the pylorus muscle is slit down
entire length (of course, only the muscle fib
are cut, not the inner lining of the stomac
The operation is very safe, and the wound h
within about a week, after which the infant
no further trouble.

The small intestine can be affected by a num
of diseases, although much less frequently t
the stomach and duodenum. Here we sh
mention only two of the more common conditio
regional ileitis and intestinal obstruction.

Regional Ileitis is an inflammation of the sm
intestine frequently found in young men
women. The cause is unknown, but it leads
ulceration and small perforations which ca
adhesions between the affected area and ot
parts of the small intestine. Such a condit
requires surgical treatment, which usually ta
the form of short-circuiting the diseased area
joining together the healthy ends of the lo
Sometimes the diseased area is cut away altoget
and the healthy end joined to the large intesti
By this means the vast majority of cases can
cured.

Intestinal Obstruction can be caused by a tumo
by a loop of intestine becoming twisted on it
(volvulus), by the bowel being caught in a her
sac, or by the contraction of old adhesions. H
too, the surgeon will either by-pass the area o
the intestine has become damaged and gangr
has set in he will remove the whole of the affec
part. Acute (*i.e.*, sudden) obstruction is
surgical emergency, and if an operation is
performed death will occur in a few days.
symptoms are severe colic, profuse vomiti
distended abdomen, and collapse; no bo
motions are passed. Chronic obstruction,
which the blockage is gradual, is usually due t
tumour; the symptoms are periodic attacks
vomiting, constipation alternating with diarrh
and loss of weight.

In children, *intussusception* is not uncomm
especially in boys under the age of two. Here
part of bowel becomes telescoped into anoth
leading to colic and the passage of motions c
sisting of blood and mucus. Later there will
vomiting and collapse. Operation, of course
necessary.

Constipation. Here, perhaps, we had bet
mention the question of constipation, about wh
so many people hold such pronounced vie
They believe that constipation is the root of
evil, that it causes a mysterious condition kno
to them (although, alas, not to doctors) as "au
intoxication." Sedulously fostered by the ma
facturers of patent medicines, their beliefs ra
from the notion that headaches, spotty sk
muddy skin, and tiredness are caused by c
stipation, to the more extreme idea that
whole system is being poisoned and that, if
bowels do not work, the individual will sho
die. Of course, all this is the merest rubbi
for, as Professor Samson Wright, whose *App*
Physiology is one of the most famous of med
text-books, has pointed out, there is no such th
as absorption of poisonous products from
bowel. There is no such thing as "auto-intoxi
tion." "The symptoms of constipation,"
writes, "are largely due to distension
mechanical irritation of the rectum." It has b
shown that an enema removes these sympto
immediately, which would not be the case if t
were due to poisons in the blood, and exactly
same symptoms can be produced by packing
rectum with cotton-wool. Wright mentions
case of a man who went for just over a year w
out a bowel motion, and at the end of that ti
although his abdomen was distended and he
some discomfort, he was not noticeably ill. Ne
less to say, telling these facts to the purga
addict will only make him annoyed, but it is
well to note that if no known diseases are due
constipation (although constipation may be
symptom of another disease), the regular use
purgatives *can* cause disease.

Constipation should be treated first by

ning plenty of roughage—bran and oatmeal
cellent—plenty of stewed and fresh fruits,
t least three pints of fluid should be taken

ath you will have mapped out is that of the
which, as the name implies, is much wider
he small intestine.
colon is just as subject to disease as the
ch. In fact, Dr. Clark Kennedy says that
o-called indigestion "is not due to duodenal
tric ulceration . . . but to disorder of the
nics of the large bowel aggravated by
ection and *again and again by the misuse of*
ts" (the writer's italics). Irritation of
lon is known as colitis, and there are two
ulcerative colitis and mucous colitis.
the case of stomach and duodenal ulcers,
factors play a large part, but, since not
ne with anxiety or who is under stress
ps colitis, we have to assume that this
ion, and indeed the other stress diseases,
used by an interplay between hereditary
ition, certain physical factors not yet
etely understood, and stress.

rative Colitis is a serious disease in which
is not only inflammation of the intestinal
t also ulceration. The patient, usually an
between twenty and forty, and most com-
a woman, develops diarrhœa, with passage
od, pus, and mucus; there is an irregular
although no germs have ever been con-
ly found to account for this. Sometimes
sease begins abruptly and ends in quite a
time in death, but more often it runs a
of many months in a milder form. Medical
ent, such as washing out the colon, may be
and various drugs have been tried, and in
75 per cent. of cases these prove adequate.
the remaining 25 per cent. of cases operation
cessary. The operation performed is
ny, in which the end of the small intestine
ght out on the abdominal wall so that the
s pass out there, the colon is thus put out
on and can be rested. In about 10 per
f cases the ulceration heals and the small and large intestines can be joined up again by closing the opening on the abdomen, but more often the opening must be permanent. If, in spite of this, the bleeding and diarrhœa persist, the only possibility is to perform a *colectomy*—*i.e.*, to remove the whole of the colon. Although this is a large-scale operation, the recovery rate is well over 90 per cent.

Mucous Colitis is a less serious disease which appears to be almost entirely nervous in origin. As in the other type, there are attacks of diarrhœa, in which quantities of mucus and membranous material—actually parts of the lining of the bowel—are passed. There is no blood, and the treatment is medical, with sedatives and antispasmodics, drugs which relax the spasm in the colon.

Appendicitis is a disease which mysteriously became popular towards the beginning of this century. Appendicitis begins with pain over the stomach (*i.e.*, in the *upper* part of the abdomen, and not over the site of the appendix). The pain remains there for some hours and then moves to the right lower part of the abdomen; there is usually fever and sometimes vomiting. It is important to realise that in any case of abdominal pain purges should never on any account be given; in appendicitis particularly purges may lead to death from peritonitis. The treatment of appendicitis is nearly always surgical, but in a few cases antibiotics may be used.

Bleeding from the Rectum is a common symptom which may be due to a number of causes: hæmorrhoids, dysentery, typhoid, some blood diseases such as purpura, and tumours. Bleeding from a gastric or duodenal ulcer leads to black motions or *melæna*. The blood in this case is black because it has been changed in its passage through the digestive tract, and although black motions may result from harmless causes—*e.g.*, when iron-containing medicines or bismuth are being taken—it should always be referred to a doctor. In fact, any bleeding from the rectum should be investigated.

Visceroptosis occurs when the bands of tissue holding up any of the abdominal organs begin to sag so that the organs sink downwards. The symptoms are vague: dyspeptic tendencies, constipation, and a general feeling of being unwell. Although it often occurs in young women who have had too many pregnancies too quickly, there is a large neurotic element involved. Treatment is directed towards the neurotic condition accompanied by exercises and perhaps the use of an abdominal belt to support the sagging muscles.

Cœliac Disease. Some children are born with an innate difficulty in absorbing fats from the small intestine. They suffer from diarrhœa, in which large quantities of partly digested fats are passed from the body. The passage of fats in this way is known as *steatorrhœa*, and the disease is described as *cœliac disease* (Gee's disease), or, if it occurs in the tropics, *tropical sprue*. Adults, too, may suffer from the disease, but in children the important factor is that the disease is also associated with defective absorption of iron and calcium, so they tend to become anæmic and may develop rickets. It is necessary to give a fat-free diet, vitamins and calcium, and plenty of protein. "Sprulac," which is a dried defatted milk powder, is frequently given. The condition may go on for years, but the outlook is quite good. Tropical sprue is not caused by living in the tropics, but tropical conditions may bring out a latent tendency to steatorrhœa.

Diverticulitis. In diverticulitis an inborn weakness of the large intestine leads to weakness of the muscular wall of the large intestine, and through the weakened areas the mucous membrane or lining of the bowel pushes through. Probably at least 5–10 per cent. of all people have some diverticulæ, but they give trouble only when they become inflamed through some of the fæcal contents of the intestine getting trapped within them. There is pain, usually in the left lower part of the abdomen, slight fever, and general abdominal tenderness. Diverticulitis can usually be treated by dieting, rest, and antibiotics or sulpha drugs. The vast majority of cases can be dealt with in this way; but if they do not respond, it may be necessary to remove the affected area.

Cancer of the Large Intestine. The large intestine is one of the commonest sites for cancer. The symptoms, which usually occur from forty to sixty, are twice as common in men as in women, and, in general (although this depends upon the part of the colon affected), they are: passing of blood from the rectum, loss of weight, anæmia, and increasing constipation. Pain occurs as the obstruction increases, and finally the signs of acute obstruction already described make their appearance. Fortunately, symptoms usually appear early in the disease, so it can frequently be caught in time. Surgery is the only remedy, and in early cases may be done in one stage by removal of the affected part, but if obstruction has begun it is necessary to perform an operation—*colostomy*—in which a part of the intestine, as in ileostomy, is brought out on to the abdominal wall, so that the fæces discharge from the side of the abdomen instead of through the rectum. This operation is followed a few weeks later by removal of the part containing the tumour.

Hernia. The body, unfortunately, is supplied with many weak areas in the abdominal wall and elsewhere through which structures such as the intestines can thrust their way to where they are not supposed to be. This condition is known as hernia. There are numerous different types of hernias; for example, they may occur in the canal below the groin through which the large blood-vessels pass back and forth between the legs and abdomen or in the larger inguinal canal just above. They are also found at the umbilicus, a weak area through which before birth the child was supplied with all its needs from its mother's circulation, or right in the middle of the abdomen below the umbilicus, where the two vertical bands of muscle which form the abdominal wall come together but often leave a weakness in between. There may also be hernias internally, or in the diaphragm, or over the site of an operation scar. In the groin we speak of *inguinal hernia*, in the area where the vessels pass between abdomen and legs slightly below the groin we speak of *femoral hernia*, at the umbilicus, *umbilical hernia*, and between the two abdominal muscles, *ventral hernia*. A *diaphragmatic hernia* is one in which the stomach pushes its way into the chest through a weak part of the diaphragm.

Hernias may occur at any age, and indeed many children are born with them. In later life they are generally caused by a combination of developmental weaknesses in the area concerned, flabby muscles, and sudden strains, such as lifting heavy weights. The main danger from a hernia, apart from its inconvenience, is that it may become *strangulated*—that is, a part of the intestine may become caught in the hernial sac, and becoming filled with intestinal contents, swell up and be unable to escape. This causes all the symptoms of intestinal obstruction and has to be treated as an emergency, or else gangrene of the part which is caught and possibly peritonitis will occur.

Although many people, fearing surgery, wear a truss—that is a belt which by pressing on the part keeps the weak area compressed—there is no doubt that hernias, except in the old and infirm, should be operated on. No matter how comfortable the truss may be, it is a continual nuisance and interferes with many activities, such as swimming; nor are trusses always adequate in performing their function. The operation involves replacing the herniated organs back into the abdominal cavity, removing the sac of peritoneum (*i.e.*, the thin lining of the abdomen which has been pushed out by the organ), and then repairing the muscle wall where it was weakened. The main sign that a hernia exists (at least so far as femoral, inguinal, umbilical, ventral, or scar hernias are concerned) is a soft swelling over the place where the weakness exists. Unless strangulation occurs, there need be no other symptoms. But any bulge in the groin or upper thigh or, indeed, anywhere, should be immediately referred to a doctor.

Cancer of the Rectum. The rectum and anus
afflicted by two common diseases: cancer of
rectum and hæmorrhoids. In cancer of
rectum the symptoms are similar to those d
cribed under cancer of the large intesti
Operation is imperative as soon as possible,
it is usual to remove the anus, rectum, and
lower part of the colon, subsequently creatin
permanent colostomy.

The anus, the last inch of the intestinal ca
is a sphincter, a band of muscle which contr
the exit of fæces from the bowels. In addition
hæmorrhoids, the anus may be the site of fissu
(*i.e.*, ulcers of the lining), fistulas (abnormal tra
leading from the lower rectum to the skin),
polyps (non-malignant growths). *Fissures*
elongated ulcers rather like a crack in the muc
lining which cause pain every time the bow
are moved. They tend, if untreated, to
deeper and more inflamed. Treatment is surgi
by cutting the sphincter muscle to allow relax
and healing. A *fistula*, as has been mentioned
an abnormal channel between the lower rect
and the skin—*i.e.*, it comes out somewhere arou
the anus. Nearly always it is the result o
previous infection, such as a boil or abscess,
the region of the anus. The treatment is surgi
as a fistula rarely clears up by itself.
channel is opened and cleared out, then pack
is put in to enable it to heal from the bottom
Polyps may vary in size from a pea to a golf b
and the first sign may be fairly severe hæmorrh
from the rectum. Sometimes there is no bleedi
but the polyp suddenly appears protruding fr
the anus after a bowel movement. It is painle
and not in itself serious, but should neverthel
always be removed (this can often be done
cauterising without an anæsthetic), since so
authorities believe that such growths may beco
cancerous.

Hæmorrhoids are simply varicose veins in
rectal and anal regions. They are very comm
and are caused probably in about equal degrees
inherited weakness of the veins, strain such
heavy lifting, and constipation (this is one of
very few conditions in which constipation may
some damage, due to the mechanical pressure
hardened fæces in the rectum on the vei
Pregnant women are liable to develop hæmorrho
or "*piles*," as they are commonly called, ow
to the pressure of the baby's head in the pel
Hæmorrhoids may be external or internal,
former being in the anal region below the sphinc
the latter in the rectum; the two usually go
gether. There may be no symptoms, but
veins are liable to bleed, to get thrombosed (
a clot forms within) or to become infect
When clotting or infection occurs the piles enla
and tend to be pushed out through the a
during defæcation, when they form extrem
painful external swellings. Treatment in sim
cases may be by the use of suppositories—co
of a firm grease containing suitable medicame
which are inserted in the rectum—in other ca
the veins may be injected, as with varicose ve
of the leg, in order to close them, but when ther
much bleeding, thrombosis, infection, or in
ference with bowel movements they should
removed surgically.

DISEASES OF THE LIVER AND GALL-BLADDER.

The functions and site of the liver have b
described elsewhere, so no more need be s
about these. Presumably the most comm
associations of the layman in relation to the li
would be the two words "liverish" and "ja
dice." Feeling *liverish*, one gathers, produce
sort of sensation like a hangover (which it
quently is), but there is no medical term co
sponding to the word, nor is there any reason
all to suppose that it has anything whatever
do with the liver. Most likely it is an attack
mild gastritis, and should be treated as such.

Jaundice is easily recognised by the yellow
skin, the degree of colouring depending upon
severity of the case. In mild cases it may only

eable in the whites of the eyes. Less well-
n symptoms of jaundice are itching of the
dark-coloured urine and pale motions,
ssion, loss of appetite, and tiredness.
dice, however, is not in itself a disease;
r it is a symptom of many diseases, amongst
some of the commonest are:

(1) Blockage of the bile ducts, which
ormally carry the bile and its pigments into
he intestines (it is the pigments which
roduce the yellow coloration). The block-
ge may be caused by gall-stones, parasites,
umours, or in the liver itself when cirrhosis
s present. The bile pigments, unable to get
hrough the duct into the intestine—hence
he pale motions—pass backwards into the
lood-stream and are filtered into the urine,
vhich therefore becomes stained, and into
he skin. This is known as *obstructive*
aundice.

(2) *Infective jaundice*, on the other hand,
esults from various types of organism such
s spirochætes and viruses. Examples are
nfective hepatitis, spirochætal jaundice,
ellow fever, malaria, and some cases of
yphilis. Certain poisons, such as chloro-
orm, arsenic, phosphorus, and snake venom,
an also cause jaundice, which in this case is
ue to damage to the liver.

(3) *Haemolytic jaundice* is found is some
lood diseases, such as pernicious anæmia,
choluric jaundice, and blackwater fever.
ts immediate cause is breaking down of the
ed cells at a rate too rapid for the liver to
bsorb the products.

treatment of jaundice depends entirely
its cause. The infective and hæmolytic
have already been dealt with under in-
us diseases and diseases of the blood
tively, so it only remains to deal with
ctive jaundice, and this leads us to the
t of the gall-bladder and *gall-stones*.
rs in their perverse way refer to inflamma-
f the gall-bladder as *cholecystitis* and to the
ion of having gall-stones as *cholelithiasis*
as Americans refer to typists as "steno-
ers" and lifts as "elevators").

gall-bladder is pear-shaped and lies below
er. It ends, at the "stalk" of the pear, in
called the cystic duct, which enters the
bile duct passing from the liver into the
ing of the duodenum. Bile is essential to
gestion of fats, and when a meal is eaten a
of dilute bile moves down the main duct
he liver, whilst more concentrated bile is
ed into the same duct from the gall-bladder.
ile, both dilute and concentrated, then
the duodenum to do its work. In chole-
s, which may be acute or chronic, the walls
gall-bladder become infected, usually by
cocci or the bacillus coli, and severe pain
ps over the liver area, typically spreading
o the right shoulder-blade. If the in-
becomes worse and pus is formed there may
high fever. Gall-stones may, as some
ans believe, be the aftermath of such an
on, although others think that they are
because of some defect in the ability of the
o deal with fat and cholesterol. In any
all-stones are formed in the gall-bladder,
ay number anything from one or two to
hundred; their size varies from that of a
f corn to that of a golf ball. Stones may
sent without causing any trouble at all,
ally sooner or later the following symptoms
): indigestion after eating fatty foods,
rn, nausea, and attacks of pain. The
gall-bladder disease, whether in the case of
infection or gall-stones, is more or less the
over the gall-bladder area and passing to
ht shoulder-blade. Such pain signifies
infection, which, of course, may occur
stones, or else that a stone formerly lying
within the gall-bladder has passed into
duct and got stuck.

cally, gall-bladder disease is found in men
men in middle age, but it is three times
ner in women. As an aid to examinations,
s are told (or used to be told) that the
case is a woman who is "fat, fair, forty,
tile," for there can be little doubt that pregnancy plays some part in upsetting the secretion of bile in some people. But it is also entirely possible for thin men to develop the disease, so there is no general rule.

When the stone blocks the cystic duct (*i.e.*, the one leading from the gall-bladder to the main duct) there is pain, which may be relieved when the stone either moves back into the bladder or passes into the main duct. The next problem is whether it can negotiate the opening of the main duct into the intestine; for if this duct is blocked *none* of the bile can escape and, passing back into the blood-stream, it produces jaundice.

Operation is necessary when acute inflammation is present, when there are frequent attacks of severe colic and other symptoms causing discomfort, or when jaundice is present. Drugs can cause only temporary relief when a gall-bladder becomes troublesome. There is no such thing as a drug which dissolves gall-stones.

The liver may be the site of cancer, but this is nearly always secondary to cancer elsewhere. Primary cancer, that is cancer originating in the liver, is not common. So, too, the liver may become enlarged, sometimes very considerably so, as a result of events elsewhere in the body: heart failure, leukæmia and other blood diseases, and even rickets can cause enlargement. In the liver itself enlargement may be due to cancer, cirrhosis, abscesses, and cysts (the former usually caused by amœbic dysentery, the latter by parasitic worms; both of which are described elsewhere). Abscesses are usually aspirated—which means that a needle attached to a syringe is passed in and the pus drawn off—cysts have to be surgically removed.

Cirrhosis of the Liver is a condition in which more and more of the liver cells become replaced by fibrous tissue. Now, as we have seen, the whole portal system which carries away the end-products of digestion passes into the liver, so when the liver becomes fibrosed there is serious obstruction to the portal circulation, leading to back-pressure in the veins, and therefore the liquid part of the blood, the plasma, oozes out through the walls into the abdominal cavity. This is known as *ascites*, and it is also found in some cases of heart failure, kidney disease, and chronic peritonitis. Formerly the fluid was removed by tapping the abdominal cavity but modern drugs for increasing fluid loss by the urine are usually successful.

Cirrhosis is always a serious disease; for, although Nature is so generous as to give us 80 per cent. more liver than we need to preserve life, the common type of cirrhosis extends right through the liver, and the secondary effect of portal obstruction with ascites complicates the matter. The disease in the West is often associated with alcoholism, especially in those who drink large quantities of spirits (there are other types of cirrhosis which need not be mentioned here); but the problem is more complicated than might appear, for everyone who drinks to excess does not develop cirrhosis. In fact, cirrhosis is not at all common, and some seem more liable to it than others. It is believed that another unknown factor, possibly malnutrition, is involved and the disease is not due solely to alcohol as such.

Symptoms are: chronic gastritis, morning sickness, constipation. Later, when the portal system has been seriously obstructed, large veins are seen on the abdominal wall, especially around the umbilicus. These develop in an attempt to compensate for the blocked portal circulation. Ascites and slight jaundice are later symptoms. Treatment is a matter for the specialist, but obviously alcohol should be banned. Recently, an operation has been devised in which the portal vein, instead of going to the liver, is sutured to the *vena cava*—the largest vein in the body, which passes up the centre of the abdomen just in front of the backbone on its way to the heart. This operation is known as *porta-caval shunt*. Not infrequently the first sign of cirrhosis is serious hæmorrhage from the mouth due to the rupture of "varices" (*i.e.* varicose veins) at the end of the œsophagus.

The Pancreas.

This is a soft, elongated gland lying behind the stomach; it is about 5 in. long and 2 in. wide.

Within its tissues lies the duct, which, when it leaves the pancreas, passes into the duodenum near the point of entry of the bile-duct. This duct transmits the juices containing enzymes which aid in the digestion in the small intestine. The pancreas, however, has two main functions: not only does it manufacture these important digestive juices, but in certain specialised areas, known as the islets of Langerhans, it manufactures insulin. The functions of insulin will be discussed shortly when we are dealing with diabetes.

Like the liver, the pancreas may be the site of cysts or tumours. The only other condition which need be mentioned is *acute pancreatitis*. This is a not very common disease which is caused by a small gall-stone becoming stuck in the opening of the duct. When this occurs, bacteria come in to infect the pancreas, and the blocking of the duct prevents the digestive juices from leaving, with the result that the organ is digested by its own enzymes. There are all the signs of an acute abdominal disturbance: sudden severe pain, vomiting, and fever. Pancreatitis is difficult, even for the expert, to diagnose, and formerly was always treated surgically, but today it is often possible to clear it up with medical treatment and the use of penicillin or other antibiotics.

Diabetes. Although we know so much about diabetes, we still have not the faintest notion as to what causes it. Its immediate cause is a failure in varying degrees of the pancreas to produce insulin, but examination of the pancreas rarely reveals any significant changes. The disease is commonest between thirty and sixty years, but may occur even in children. Now, insulin is the substance which makes it possible for the body to make use of sugar—the glucose which is the end-product of carbohydrate digestion. So in its absence the glucose, although there to be used, is useless to the body and accumulates in the blood, finally passing out in the urine. (The fundamental test for diabetes is the discovery of sugar in the urine by the use of certain simple procedures.) The diabetic, then, is being starved of sugar no matter how much he takes in, and the excess sugar in the blood which cannot be used acts as a poison, which, in extreme cases, sends the patient into coma and may—indeed, in former times, usually did—result in death. The symptoms of diabetes vary, of course, with its severity, but in the main they are: increasing appetite in an attempt on the part of the body to supply the sugar which is there but so tantalisingly unavailable, great thirst, because this useless sugar has to be excreted, and the production of urine demands water, frequency in passing urine, and increasing loss of weight in spite of all that is taken in. In severe and untreated cases boils, itching of the skin, gangrene of the limbs, and finally coma and death may occur.

Although mild cases of diabetes could, and still can, be treated by dieting alone, by reducing the intake of carbohydrate, the diagnosis of diabetes prior to 1922 amounted almost to a death-warrant. In that year, however, the Canadian physicians Banting and Best separated out the secretion of the islets of Langerhans and named it " insulin "; they showed that insulin taken from the pancreas of animals and injected into the diabetic patient was just as effective as the home-made article.

Since a diabetic regime has to be decided on by the doctor according to the severity of the disease, no useful purpose would be served by discussing the details of diet or dosage of insulin, which vary from one person to another. On the whole, diabetes is more severe in young people than in the elderly, but with correct treatment it is possible for all cases to lead a perfectly normal life except in so far as dietary restrictions and insulin injections are concerned. Many famous people are, or have been, diabetics—for example, H. G. Wells—and have lived to a ripe old age. Recently, a drug has been discovered which has the great benefit that, unlike insulin, it can be taken by mouth.

Whereas the type of diabetes we have been describing, the disease ordinarily known by that name, is properly known as *diabetes mellitus*, there is another disease known as *diabetes insipidus*, which, in fact, has no real relation to the other at
all. In this disease there is no sugar in
urine, nor has it anything to do with the pancr
Diabetes insipidus is a rare disease character
by the passage of large amounts of dilute u
and appears to be due to deficiency of the se
tion of the posterior part of the pituitary gl
at the base of the brain. It can be parti
controlled by the use of pituitrin.

Peritonitis is an infection of the peritoneum,
thin, transparent lining which covers all
abdominal organs. Acute peritonitis may oc
at the end of serious chronic diseases, but m
commonly it arises from perforation of some
of the intestines or stomach which allows se
material to flow into the abdominal cavity,
from extension of infection from the Fallop
tubes (the tubes passing between ovaries and wo
in women). Wounds of the abdomen are als
possible cause. There is severe pain, vomit
constipation, fever, and the abdomen is distend
The coils of intestine become matted together
infected lymph, produced by the germs wh
while harmless within the intestine, are danger
to life outside them. Treatment may be by a
biotics or surgery or both.

Chronic peritonitis is usually tuberculous
origin, and is commonest in young children.
is usually caused by the bovine type of bacil
and usually there is ascites (*i.e.*, free fluid in
abdomen), with slight fever. Matting toget
of the intestines may threaten to produce
struction. Unlike acute peritonitis, in wh
death will occur within two or three days with
treatment, chronic peritonitis is a long-drawn-
disease which is usually treated medically.

DIET.

Food, like alcohol, tobacco, and constipation
one of those subjects which people tend to hav
" thing " about. In point of fact, what we kn
at present about this subject may be summari
as follows: Any diet to be adequate must firs
all provide enough energy, and energy is measu
in terms of Calories (for definition of a Cal
see Gen. Inf.). Thus a ten-stone man leadin
moderately active life will require about 3,
Calories daily; that is the amount of energy
requires in order to carry out his work and av
living on himself, on his stored-up food.
amount of Calories required varies with age, s
and the amount of work done, from 1,
Calories for the light-weight sedentary worker
three or more times this amount for the he
manual worker.

Now, in theory, the adequate amount of Calo
could be supplied from carbohydrate and
alone, since, as we have seen, Calories are me
a measure of energy and can be supplied by
food. But in this case the individual would
live long, because he needs for body maintena
certain kinds of food in adequate proporti
Just as you cannot run a car for long simply
putting in petrol and ignoring lubricating oil
maintenance of the engine, so you cannot
your body simply by taking in enough Calor
There must be adequate proportions of the th
basic foodstuffs: carbohydrates (the fuel),
(for insulation and other purposes), and prot
(for body-building purposes). Proteins

contain nitrogen and the others do not.
could even live on a diet of nothing but protein,
not on a diet of fat or sugar; proteins are a
logical necessity. It is generally agreed tha
well-balanced diet should provide 25 per cent o
energy from fats, 10–15 per cent from proteins,
the remainder, 60–65 per cent, from carbohydra

Here are some foods classified according to
predominating basic foodstuff they contain:

(1) *Carbohydrates:* bread, sugar, and
starchy foods or sweet things such as
fectionery, puddings, and cakes.

(2) *Fats*: animal fats, such as dripping,
t meat, fried foods, butter, margarine, and
egetable oils, such as olive oil, or fish oils,
hich are found more in some fish than others
-*e.g.*, herring.

(3) *Proteins*: lean meat, cheese, non-fatty
sh, nuts, oatmeal.

ddition to these basic foods, the body must
ave adequate supplies of vitamins (P42, 62)
ertain minerals, such as iron, manganese,
n, copper, sodium, potassium, iodine, and
nate.

sity. Many people worry because they are
eight, and statistics show that the expecta-
f life is shorter in fat people than in thin
This, however, is a statistical view, and
not apply to any single person. Thus a
s French gourmet who weighed twenty
died recently at the age of eighty-two—
h falling out of a window. When one sees
who are constantly worrying about their
and diet one recalls the statement attri-
to Winston Churchill as a recipe for a long
rink too much, smoke too much, and work
He might have added ". . . and stop
ing." There are few people more pathetic
hose who, by rigidly adhering to the so-
rules of health, seek to eke out a life which,
oes not actually last longer than that of the
care-free individual, will certainly seem
longer.

ng overweight is due to one cause—eating
uch, and especially eating too much of the
kinds of food. There are, obviously, some
who can eat to their heart's content without
ing fat, perhaps because their bodies burn
food more quickly. Their *basal metabolic*
vhich is the measure of the speed at which
ody cells work, is higher than normal, and
asal metabolic rate is largely dependent on
nctioning of the glands—in particular, the
d. Nevertheless, being overweight means
you are eating too much for you; that
intake of Calories is greater than your
t.

ucing is not difficult, but it does require an
of will. Basically it depends on: (*a*) taking
od, and (*b*) taking food which is not fat-
cing. In practice, this means taking a high-
n diet, little fat, and no sugars or starches.
diet would be somewhat as follows: coffee
with milk, but *no sugar* for breakfast, and
ired, Energen rolls or Energen crispbread,
er of rye or wheat, but *no white or brown*
A small amount of butter or jam may be
with the crispbread. At lunch, grilled lean
or an egg dish and salad, followed by jellies
it or crispbread and cheese—but *no potatoes.*
vening meal may consist of grilled or steamed
lear soup, cheese, fruit, but there must be
ed foods and no sweets at any time. This
s merely to give an indication of general
ples: more interesting ones will be found in
ges of most women's magazines or from time
e in the daily papers. The basic principles
ovious: plenty of lean meat, non-fatty fish,
cheese, fruit, Energen rolls or crispbread (the
ry crispbread is just as fattening as bread
, but no fried foods, fat meat or fish, bread,
oes, sweets, or cakes. However, small
nts of butter and quite a lot of milk are
ssible, and the modern tendency is to ignore
take which, by reason of its nature, is self-
ng.

sity may have a psychological basis, and
ive eating is often a substitute for affection
ividuals who have been spoilt as children.
owever this may be, most people find it as
lt to stick to a reducing diet as they do to
up smoking. For such people there are
n drugs which may help. Thyroid tablets,
generally used for reducing, are little used
and should be used only when the thyroid
is underactive; otherwise they simply
se appetite, and although they speed up the
stion in the body (the basal metabolic rate),
fect is cancelled out by the increased appetite.
rene, one of the derivatives of benzedrene or
etamine, acts by reducing the appetite, but
ne people of a nervous disposition it may have the effect of causing a feeling of tenseness, and they may even have difficulty in sleeping. Finally, there is a substance obtainable at chemists' shops without prescription either in the form of granules or biscuits which does not exercise any chemical effect on the body; what it does is to swell up into a gelatinous mass within the stomach under the influence of water, which is drunk later, and this gives the impression of a "full stomach" and allays the pangs of hunger.

There are, as has already been mentioned, many fads about food, although one is treading on dangerous ground when one mentions them; for every faddist is a fanatic, and every argument one may put before him is seen as an attack on himself. For example, there was the "Hay diet," now, it appears, largely forgotten; then the "Gaylord Hauser diet" much favoured by Americans, which seems to be based largely on large quantities of molasses and brewer's yeast; and there was not so long ago a gentleman who lived on grass freshly clipped each morning from Hyde Park—it would be interesting to know whether he has survived his self-imposed ordeal. However, few doctors would deny that, although diet in some cases is an adjunct to the cure of disease (for example, peptic ulcer, diabetes, sprue), it is not a cure for disease, and those who make such claims are claiming a great deal too much. It must be repeated that, so long as a diet contains adequate amounts of the basic foodstuffs, adequate amounts of vitamins and the necessary minerals, and so long as it supplies adequate Calories for the build of the individual and the amount of work he does, it matters very little how these needs are supplied.

Vegetarianism.

This can hardly be called a fad, although it cannot be denied that many of its adherents are faddists. It apparently has two main sources. There are those who abstain from animal food for moral reasons because they believe that killing is wrong, even for food; and there are others who believe that vegetable food is more healthy than animal food. Some vegetarians live almost entirely on vegetables and fruits, whilst others allow themselves milk, eggs, and cheese. The moral issue cannot be argued here, although it must be admitted that few people who have visited a slaughter-house for the first time have as much appetite for their steak the day after, so we shall only discuss the health aspects of vegetarianism. On the negative side, it must be said that, in general, vegetable foods are much less rich in protein than animal foods, so one has to eat a great deal more in order to get an adequate amount. If, however, one includes in a vegetarian diet cheese, milk, and nuts or eggs this difficulty is largely obviated. Cows and other animals living on grass or vegetable matter have to spend practically their whole lives eating, precisely because they would not otherwise get sufficient protein. On the positive side we have the as yet unconfirmed assumption that, in predisposed people over forty, excess of animal fats can lead to cholesterol being deposited in the blood-vessels, notably the coronary vessels in the heart, and thus to coronary thrombosis. Vegetable and fish oils do not seem to have this effect, hence the infrequency of thrombosis amongst those peasants in Europe who are too poor to afford much meat and amongst the Eskimos who eat fish. From the point of view of evolution it would seem that Man is designed to be both carnivorous and vegetarian; for he has sharp, cutting teeth in the front for tearing meat and flat, grinding teeth at the back for dealing with grains. We must conclude that those who are vegetarians for moral reasons should have all our respect; for killing is not a pleasant thing, and we have already too much of it. From the merely medical point of view vegetarianism has both advantages and disadvantages. Nobody will suffer from being vegetarian, but, apart from the exceptions mentioned, there is little reason to suppose that their health will be any better than that of meat-eaters. We are less able to influence our fates than we often suppose, since longevity and good health are much more a matter of heredity than is ordinarily believed.

THE DEFICIENCY AND METABOLIC DISEASES

INTRODUCTION.

If you have read earlier parts of this section you will know that there can be two types of malnutrition; the first, of course, is the type we ordinarily think of when the word is mentioned, and in this case the individual is simply not getting enough food or enough of the right kind of food. The second type might well not be regarded by most people as malnutrition; for here we are referring to diseases such as diabetes and sprue, in which, although there is adequate supply of certain foods, the body, owing to some deficiency, is unable to make use of them. The patient with diabetes cannot make use of sugar, the patient with sprue of fat—they are starving in the midst of plenty, as is shown by the fact that in both cases one of the prominent symptoms is wasting.

We shall deal first with the ordinary type of malnutrition and later with the second. Since diabetes and sprue have already been mentioned, we shall be looking at some other conditions in which something or other is missing or is present in the wrong amounts, as in the diseases of the endocrine glands.

Two-thirds of the population of the entire world are undernourished, and particularly in Asia famines are common—famines like the one in Bengal in 1943, in which 3 million people died of starvation. In Europe such conditions exist only when war dislocates food supplies, but nevertheless individual cases of malnutrition can occur. For example, the lazy or ignorant mother of a large family may feed them largely on bread and margarine, with no fresh fruit or vegetables and only tinned meat because she "can't be bothered" cooking. Or the self-sacrificing mother of a large family may give all the meat and protein food to her working husband (somehow or other many men fail to notice that a housewife works!) and her children. Then old people or people living alone are liable to neglect their food, either because they have lost heart, because they are too frail, or because they cannot afford to buy enough good food. Lastly, those who are addicted to alcohol neglect their food and, drinking on an empty stomach, soon get such a degree of gastritis that they find it difficult to eat even when they need to.

A human being can live about six weeks without food, and a much shorter time—a week or ten days—without water. Naturally, human nature being as it is, there have been many claims to longer periods of starvation, and some of the more enthusiastic claim not to eat at all! Thus, in the sixteenth century Eve Fliegen of Brabant appears to have lived for fourteen years solely on the smell of a rose, and, coming nearer our own time, Mollie Fancher of Brooklyn, who died in 1916, similarly lived for fourteen years without eating, and in 1864 even stopped breathing. However, presumably becoming bored with this, she resumed her respirations after only fourteen weeks.

These people, needless to say, were humbugs, as is revealed by the grim case of Sarah Jacob "the Welsh Fasting Girl," who towards the end of last century allegedly took no nourishment whatever for two years, two months, and one week. The one week, at any rate, is certain; for, at the invitation of the local vicar, who was convinced of her genuineness, a number of doctors from London came to observe her. They put relays of nurses to sit by her bed day and night to note whether she ate, but in a few days she began to decline so alarmingly that the doctors begged the parents to feed her. This they refused to do, and Sarah would not ask for food. She died within a week on December 17th. The most famous non-eater of today is Theresa Neumann, who lives in Bavaria and claims that nothing but the wafer, the Eucharist, at Holy Communion has passed her lips since 1927. The Roman Catholic Church, however, has been careful never officially to recognise her claims as true. So we shall still assert that six weeks, more or less, is the longest period a human being can go without eating.

DEFICIENCY DISEASES

The materials which are necessary to the body have been mentioned elsewhere, and, we can
now look at some of the diseases (other th
those already discussed) which result from th
lack.

Lack of iron leads to anæmia, but less w
known is the type of deficiency caused by lack
iodine. Iodine is found in large amounts in s
weed, which obtains it from the sea surroundi
it and concentrates it in its fronds. But ordina
water contains enough for our needs. In so
districts, however, especially where the main ro
is limestone—Derbyshire and some valleys
Switzerland and the Himalayas—the wa
contains very little iodine, and there the inha
tants are prone to develop goitre. There a
several types of goitre, but this type is caused
lack of the iodine which is necessary to build
thyroxin, the secretion of the thyroid gland. It
a deficiency goitre known in adults as myxœdem
but in those parts where iodine is lacking in t
water supplies the disease develops in childho
and the children become, although perfect
normal when born, dull, gross, and stupid—th
become idiots or, as they are more correct
described, cretins. This is one of the commone
types of mental deficiency in children, and,
noted in time, they can become completely norm
by the use of thyroxin or thyroid tablets. B
prevention is better than cure, and this terri
disease has now been almost eliminated in t
districts where it used to be prevalent by addi
iodine to the water supply of towns and villag
by giving iodised chocolate at schools, or oth
wise supplying the missing element.

In this country cretinism and myxœdema a
found in individual cases for reasons other th
lack of iodine: in children, cretinism may be d
to congenital lack of the thyroid gland or ea
failure, in adults myxœdema may occur when t
gland, usually in the middle period of life, ru
down. Both conditions can be treated
thyroid tablets, which, like insulin, have to
taken for the rest of the patient's life.

Lack of calcium is less common in this count
than it once was. Calcium is necessary
building the bones: it is calcium, in fact, th
makes the bones hard. Actual lack of calcium
the diet is very rare, because calcium is one of t
commonest elements in Nature, and what usua
happens is that lack of vitamin D or calcifer
without which calcium cannot be utilised
absorbed, causes the deficiency.

The two main diseases caused by calcium,
rather vitamin D, deficiency are rickets a
osteomalacia. Vitamin D is found in fats—
only animal fats such as are found in meat, f
and milk; it is not found in vegetables, plants,
fruit. A second source of the vitamin is sunshi
or ultra-violet light, which manufactures it in t
skin; hence, in spite of inferior diet, rickets a
osteomalacia are perhaps less common in sun
countries. In *rickets*, a child during the peri
when its bones are developing does not get enou
vitamin D and cannot make use of the calciu
taken in. Its bones become soft and are liable
bend, producing defects such as bow legs, curvatu
of the spine, and deformities of the chest (pige
chest, funnel chest). In bad cases the skull
deformed and assumes a square shape. Rick
is rare today, at least in Britain; it is prevented
taking vitamin-D-rich oils, such as cod-
halibut-liver oil, or the vitamin can be taken i
more or less pure form in capsules.

In these days when diets are adequate, wh
children get cod-liver oil at home or school, a
when they are much more often in the sunsh
than used to be the case, it is not always realis
that *overdosage* of vitamins, especially vitamin
is possible. In its extreme form this is a r
condition, but children have died from overdo
which caused calcium to be laid down where it
not belong—in the kidneys and elsewhere. I
possible to have too much of anything.

Rickets is uncommon in adult life because
demand for calcium is less than in the grow
child. But in pregnancy the demand increas
and especially in Eastern lands, where famin
frequent and where, although there is plenty of s
shine, the women are veiled from any of the su
rays, there may occur the disease of *osteomala*
In this disease the bones soften and deformi
occur which are particularly important in the c
of women, in whom the pelvis becomes deform
with resultant difficulties in child-birth. Ost

ia is a main cause of the high maternal and
mortality in such countries as India.
ld people who do not get enough food, lack
min D causes no deformity, but leads to the
ion known as *osteoporosis*, in which the
through lack of available calcium, become
and break easily.

vy is another once-common deficiency
e which is now rare except under such
al conditions (or perhaps not so unusual in
days) as life in concentration camps or
st prisoners-of-war. It is due to lack of
n C, which is found in fruits and vegetables,
ularly in lemons, oranges, tomatoes, and
s. In scurvy the gums swell and bleed,
is increasing anæmia, and spontaneous
s, due to hæmorrhage under the skin, occur.
mer times the disease was the bugbear of
and travellers, because on long journeys or
es before means of preserving food were
other than drying or salting no fresh fruit
ailable. It was no less a personality than
n Cook who on his long voyages found that
nple use of lemons or limes would prevent
isease. Hence the almost international
otion of Englishmen as "Limeys"—a name
is not always used flatteringly, but of which
ve every reason to be proud. Minor degrees
vy may occur in British children even today
h faulty diet, but this is much less common
orange, blackcurrant, or rose-hips syrups
e available to all.

now come to the B group of vitamins.
are, regrettably, many members of the
n B family, but we shall mainly deal with
ns B1 and B2.

-beri is caused by lack of vitamin B1,
is found in most grains, principally in the
o and the outer covering. Now, since many
are snobs, who prefer white bread to
neal and polished rice to the crude article,
become the habit to remove the precious
covering of the grain and its embryo which
n the vitamin: white bread and polished
ok so much better. Thus, in those parts of
here rice is the staple diet, it was frequently
ne-milled, with loss of the vitamin, and the
was the serious form of neuritis known as
eri. Just as Captain Cook eradicated
from his men by the use of citrus fruits,
1882, Takaki eliminated beri-beri from the
ese Navy by giving a good mixed diet.
ed two Dutchmen, Eijkman and Grijns, to
the disease experimentally. They found
owls fed on polished rice developed the
e, whereas those fed on rice with the husk
t. In this country we are still in the rather
position of carefully removing the vitamin
efining" the flour and then replacing it
ally. However, although whole-meal bread
ably better, there is really little risk of any
ean diet lacking vitamin B1.
symptoms of beri-beri are neuritis (*i.e.*,
ration of the nerves), which leads to weak-
f the muscles, wasting, and sensations of
and needles"; the heart muscle is also
d and œdema—swelling of the limbs—or
s (fluid in the abdomen) occurs.

agra. Vitamin B2, or rather the vitamins
B2 group, of which the main ones are
vin and nicotinic acid, is another substance
ncy of which in this case leads to pellagra.
a is found in those parts of the world
maize is a staple diet, that is in parts of
a and the Far East and round the Mediter-
. Maize does not contain the vitamin
like vitamin B1, is found in most other
and vegetables, but, since vitamin B2 is
rmally produced by the action of bacteria
human colon, it would appear that there is
other factor than the mere absence of the
nce from the diet. Probably maize con-
substance which prevents the absorption
vitamin from the colon.
pellagra there is wasting, soreness of the
, diarrhœa, skin rashes on the hands, fore-
face, and neck. In severe cases insanity
may occur. The disease does not occur in this country in its full-blown form, but minor degrees may develop with the use of certain antibiotics, such as chloramphenicol and aureomycin, which kill the "good" vitamin-producing bacteria in the intestine as well as the disease-producing ones.

Vitamins.

Whereas vitamins B and C are found mainly in vegetables and fruits, vitamins A and D are found in oils and fats. Vitamin A is, indeed, found in the form of carotene in all green vegetables, but it is not much use to us until it has become concentrated in the fat and milk of the animals who eat the vegetables. Lack of the vitamin leads to *night-blindness*, to difficulty in seeing in the dusk. This is because the retina, the "mirror" at the back of the eye, requires adequate amounts of a substance known as visual purple for its full efficiency, and visual purple is manufactured from vitamin A. (It must be noted, however, that not all cases of night-blindness are due to lack of vitamin A—there is often a very large neurotic element, and it was frequently found during the War that men who on this account pleaded their inability to carry out sentry duties at night might show a very considerable talent for seeing their girl-friend at the camp gate even in pitch darkness.) Vitamin A is also connected with the health of the skin and the ability of the body to resist diseases of the respiratory tract such as bronchitis. Like vitamin D, it is most easily obtained from fish oils, such as halibut-liver oil.

Lesser-known vitamins are vitamins E and K. The former, found in wheat-germ oil, influences fertility; the latter influences the clotting power of the blood and the healing of wounds. Most vitamins can now be produced in the laboratory synthetically; in the case of vitamin B1 from coal-tar.

It is important to realise that vitamins, although necessary to health, are not cure-alls. There are few sights more ridiculous than the fad of over-fed individuals taking vitamin pills as a tonic to keep themselves up to scratch. Any vitamins taken in excess of requirements may either cause damage —as in the case of vitamin D—or else are simply excreted from the body. Extra vitamins are not a tonic, those who take them in excess are simply wasting their money, and if one eats a good mixe diet they are totally unnecessary.

GLANDULAR DISEASES.

The Endocrine Glands.

The workings of the body are regulated in all sorts of different ways—by the nervous system, the circulation, and by the endocrine glands or ductless glands, as they are sometimes called. We have already seen that there are glands, such as the liver (the largest gland in the body) and the pancreas, which manufacture substances and pass them through a duct or tube to their destination. But the ductless glands, as their name implies, have no duct and pass their secretion directly into the blood; the pancreas, for example, discharges the pancreatic fluid down a duct, but it also produces insulin, which is secreted directly into the blood. It is thus partly an endocrine gland and partly an ordinary one. The other endocrine glands are particularly important in that they produce hormones (the word means "chemical messenger"), which have a great deal to do with personality and health.

Myxœdema, we saw, is due to lack of thyroid hormone either because the gland, which is situated at the base of the neck astride the windpipe, has failed or because it has insufficient iodine to manufacture its product. The opposite effect occurs when the gland becomes overactive, and then we get a quite different state of affairs: instead of being dull, slow-witted, and flabby-looking, the patient with an overactive gland—*exophthalmic goitre* or *thyrotoxicosis* is excitable, nervous, flushed, and thin. The eyes become prominent and bulge forward, giving a staring, scared look. The disease is commonest in young adults, mostly women, and its origin is often associated with an emotional shock. Thyrotoxicosis is not primarily a disorder of the thyroid gland, and it is likely that the sequence of events is: emotional shock, which influences the nerves supplying the pituitary gland at the base of the brain, overactivity of the pituitary with overproduction of the hormones, which in turn affect the thyroid. (The pituitary is the main endocrine gland in the body and gives off hormones which control all the other glands—it has been called the "conductor of the endocrine orchestra.") All the body processes—the basal metabolism—are speeded up in this disease, which, however, cannot be treated at its roots in the pituitary. Sometimes it can be treated medically by the drug thiouracil, which damps down the activity of the thyroid, but more usually an operation is necessary to remove part of the gland. It is also possible in suitable cases to give the patient radioactive iodine—a radio-isotope which is carried, as all iodine is, to the gland, where it destroys some of the overactive tissues. The results of these procedures are good, but any exophthalmos, the prominence of the eyes, which may be present always remains.

A similar condition, appearing in middle age, may result, not from shock or from an overall enlargement of the gland, but from a *toxic adenoma*, which is a simple, non-malignant tumour. In this case exopthalmos does not occur, but the tumour should be removed. Malignant tumours also occur.

The Parathyroid Glands.

We have already discussed the importance of calcium in the body and seen how vitamin D is necessary for its utilisation. But the calcium content of the body is controlled by another factor, the parathyroid glands—two pairs of small glands lying behind the thyroid. Now, calcium, in addition to building the hard structure of bones, has another function in that it acts as a kind of sedative, damping down the nerves and preventing overexcitability. When the parathyroid glands do not work properly, or when they have been partially removed during a thyroid operation, *tetany* (not to be confused with tetanus) arises. The hands and feet go into spasm and there may be generalised convulsions. Tetany can be produced in a number of other ways which influence the amount of calcium in the blood: for example, alkalosis when people have taken too much alkali for stomach disease, or when they have lost acid through persistent vomiting, or even by overbreathing—*i.e.*, persistent deep and rapid breathing, which causes the body to lose carbon dioxide—a condition which may occur in hysterical or neurotic patients. The treatment is to give large amounts of calcium and vitamin D.

Overactivity of the parathyroid glands, usually due to a tumour, causes the reverse effects. The blood calcium is high, but this calcium has been withdrawn from the bones, and a disease known as *generalised osteitis fibrosa* arises, in which the bones become soft and there is pain, fractures, and deformities. Sometimes cysts form in the bones. The treatment is operative removal of the tumour.

Salt is very important in the running of our bodies. Indeed, our blood has been described as an "inner sea"; for, whereas primitive creatures in the ocean, such as sea-anemones and sponges, get their sustenance from the sea surrounding them and do not need a blood-stream within, in the course of evolution the situation gradually changed. As sea-animals grew bigger, the water outside did not suffice, and they had to develop some sort of circulation within; even more so, when they developed into land animals they had to carry their sea about with them. Loss of the salt in this inner ocean is occurring all the time, both through the urine and through sweating. Workers who do heavy jobs in a hot atmosphere lose a great deal of salt through sweating, and if afterwards they drink a great deal of water the remaining salt in the body becomes even more diluted, with the result that they will get painful cramps. Similarly, diarrhœa or prolonged vomiting can bring about the same result through
loss of salt from the body. After long periods
exercise it is much more refreshing to ta
water with added salt than to take pure wat
which will increase rather than diminish c
fatigue.

Suprarenal Glands.

A glandular disease which influences the bala
of salt in the body is *Addison's disease*, nam
after the famous English physician who fi
described it. This disease is characterised
great weakness of the muscles, tiredness, loss
weight, low blood-pressure, and a brown pigmen
tion of the skin. Until recently it was alw
fatal. Addison's disease is caused by damage
the suprarenal glands, two small glands wh
sit one on top of each kidney like little coc
hats. These glands produce a number of h
mones, one of which controls the excretion
salt from the body; if it is lacking, too much s
escapes, with the results described above. T
disease is now treatable by the use of cortiso
one of the suprarenal hormones.

These glands consist of an inner part or medu
which secretes a hormone known as adrenali
the substance which, when released into the blo
prepares us for states of emergency. It reinfor
states of anger or fear, and aids in the process
fighting back or running away. The cortex (
word means "bark of a tree"), on the other ha
secretes a number of hormones, one of which,
we have seen, is connected with the salt cont
of the body and another which plays some p
in sexual development. Thus a tumour of t
area may bring about a state of *hyperadrenia*,
which excessive secretion leads to premature
excessive development of masculine sexual tra
Boys show precocious sexual development, th
voice breaks, and their muscular developm
increases. Girls assume male characterist
This is known as the *adreno-genital syndrome.*

The Pituitary Gland.

The pituitary gland, lying at the base of
brain, is only about the size of a small che
yet it not only regulates the behaviour of all
other glands but is responsible for sexual deve
ment and growth. It consists of two parts,
anterior (which does all the interesting thin
and the posterior, which secretes a hormone kno
as pituitrin, thus raising the blood-pressure
causing the muscle of the uterus to contr
Many conditions are described in which
anterior part of the gland either produces
much or too little of its hormones. For exam
when this part overacts in early life the result
giant—*i.e.*, anyone over 6 ft. 8 in. In later
when the bones are set, the result of overactio
acromegaly, in which the face is elongated,
hands are relatively huge, as also are the f
The head, too, is large, and the patient give
somewhat gorilla-like impression.

When the anterior part of the pituitary un
acts there are many unpleasant possibilities:
individual may develop into a fat boy, like
one in *Pickwick Papers*, sleepy, greedy,
monstrously fat; or into a human skeleton
appears to have hardly any flesh at all; or th
may develop painful masses of fat in the wr
places, a condition described as *adiposis dolor*
or again, dwarfism may result and the individ
retain the appearance and size of a child
normal adult mentality. These conditions
known by the various names of *Frölich's syndr*
in the fat-boy type, *Simmond's disease* in
human skeleton, *Dercum's disease* in the case
adiposis dolorosa, and *Lorrain's disease* in the
of dwarfism.

The Sex Glands.

In women these are the ovaries, and in man
testes. The ovaries produce two hormones,
of which, œstrin, brings about, under the
fluence of the pituitary, the normal sex change
puberty, controls the release of the ovum from
ovary, and, in animals, produces sexual exc
ment. The other, also controlled by the pituit
is progesterone, which in general has a seda

: it prepares the uterus for pregnancy, and, a pregnancy exists, maintains it.

e internal secretion of the male sex glands is sterone, and it, like œstrin, produces the sex ges at puberty. The problems of sex, ver, will be discussed later.

ISEASES OF THE URINARY SYSTEM.

eryone knows what kidneys look like—in the term "kidney-shaped" is used to des- other objects. Within the kidneys the blood- ls carrying waste materials subdivide and y end up in little coils or glomeruli through n waste products are filtered into the other m, the system of tubes which, beginning as cups around the glomeruli, become larger arger until they join the ureter passing out e oot of the kidney, the hilum, a point at n both the veins and tubes enter and leave. kidneys, of course, lie one on each side in the so that if one puts one's hands on the hips hen slides them farther back they will cover area over the left and right kidney. The rs pass down on each side to the bladder, n is the storage tank of the products excreted e kidneys, and lies in the mid-line down low e abdomen; it is somewhat pear-shaped, and base in men there lies the prostate gland— nd which apparently has few functions but oe a nuisance. Its only known function is it adds something to the semen from the s without which the semen would be sterile. , from the base of the bladder a single tube, rethra, passes to the outside. One can, in visualise the urinary system as a capital Y, ich the two upper limbs are the ureters, the where they meet is the bladder, and the limb at the foot is the urethra. Clearly, there may be diseases of the kidneys, of reters, of the bladder, of the prostate gland, the urethra.

e amount of urine may be increased or ished. It is *increased* in the following tions: after drinking excess of fluids; after g drugs (known as *diuretics*) which are to increase the flow; in diabetes of both —mellitus and insipidus; in some types of ic kidney disease; and finally, in emotional s of excitement. It is *decreased* in the ving conditions: acute nephritis; any dis- in which fluid is being lost in other ways, as diarrhœa or sweating in fevers; when the intake is small; and when both ureters are ed by stones. Passing a great deal of urine own as *polyuria*, passing very little as *ria*, passing frequent small amounts is y called *frequency*. Normally, the urine is but in infections of the bladder it may ne alkaline owing to decomposition by ria. Abnormal substances, or normal ances in abnormal quantities, may occur in rine and give the doctor an indication of is wrong. In fact, urine analysis is a very rtant part of medical diagnosis. Thus urea ormal content of urine which is increased in , wasting diseases, or diabetes; the amount ea is to some extent a measure of the degree sue breakdown. Uric acid is found in small ities in normal urine, but the amount is ased in fevers and after an attack of gout acid is important in the causation of but has nothing at all to do with rheuma- in general, so one may disregard the ad- ements in the popular Press showing asant pictures of joints with sharp crystals c acid which are alleged to cause the pain of natic disease). Oxalates are not ordinarily in urine, but, since they occur in such foods ubarb and strawberries, and some people are e to deal with them, such individuals may op stones or have pain on passing urine after oxalate-containing fruits.

o very important substances which ought be in normal urine are albumen and sugar. nen is a protein, and its presence in the urine tes that the filters of the kidney are leaking y are allowing protein to pass out which to remain in the body. Albumen is easily for, and its presence may indicate kidney e or nephritis as it is usually called by rs. On the other hand, small amounts of albumen occur in fevers and in nervous conditions —*functional albuminuria*. Sugar, too, should not be present, but its presence does not necessarily indicate diabetes; for small amounts may occur in nervous conditions or in some people after taking large quantities of carbohydrate.

Blood in the urine may give it an appearance which varies from bright red to a dark, smoky colour. It is found in many diseases: acute nephritis, stone, tumours, poisoning by certain drugs, infections such as bilharzia or malaria, papilloma (*i.e.*, non-malignant tumour of the bladder), after injury, in high blood-pressure, scurvy, and blood diseases. Sometimes it cocurs for no known reason at all.

It will be remembered (or if it is not, you can look it up on p. 28 (1)) that streptococcal infection of the throat may cause in some people disease of the valves in the heart or endocarditis. In such cases, although the germ is found in the throat, it is not found in the heart or indeed anywhere else in the body. *Acute nephritis* occurs in the same circumstances, with the sole difference that the kidneys instead of the heart are affected. The disease appears to be an allergic reaction to the toxins of the streptococcus. The patient, often a child, has a sore throat (and even this may be absent or fail to be noticed) or sometimes the infection may arise in other sites: after scarlet fever, erysipelas, burns, and disease of the ear. A few days later there is headache, vomiting, pain in the loins, slight rise in temperature, and especially typical is *dropsy* or œdema. This begins in the face, first around the eyelids, and then affects the ankles; later it may become more general and affect the rest of the body. Blood and albumen are found in the urine, and the blood-pressure is slightly raised. The outlook is usually good if the kidneys are rested by reducing the amount of protein taken in and also the amounts of salt and water. When this is done, the inflammation soon goes and no permanent harm results. In other cases, however, if treatment is inadequate or the condition severe, the symptoms may go, but the albumen found in the urine persists. This means that permanent damage has been done, and although there may be nothing else to show for many years, *chronic nephritis* develops. In this case, the blood-pressure continues to rise, and since the filters of the kidneys no longer work efficiently, urea, the principal waste-product of the body to be excreted in the urine, is retained in the blood and only small amounts escape from the system. Hence chronic nephritis sooner or later leads to heart failure or hæmorrhage in the brain from the rising blood-pressure, or to the form of poisoning known as *uræmia* which results from the retention of urea in the blood. Uræmia may come on suddenly or gradually, but ends in progressive coma, drowsiness, and unconsciousness. There may be convulsions similar to those of epilepsy, high fever, and difficulty in breathing to complicate the picture.

Another type of nephritis which seems to have nothing at all to do with streptococcal infections, and the cause of which is completely unknown, is *nephrosis*. Developing in early adult life, its onset is insidious, and the patient first shows signs of œdema in his white and puffy face and the swelling of his legs. (It should be said here that if you have swelling of the ankles or elsewhere, you would be foolish to jump to conclusions; for such swelling is common in many diseases—in heart disease, in allergic conditions, in neurotic illness, and even just from hot weather.) When the urine is examined in a case of nephrosis it is found to be full of albumen and, as in chronic nephritis, the blood urea starts to rise. The end-results of nephrosis are the same as those of chronic nephritis and depend upon the damage originally done.

The modern diuretics of the chlorothiazide group help to control the œdema and, provided enough healthy tissue remains, remove both the fluid and the waste-products. In advanced or more serious cases artificial kidneys can be used; but as yet the transplantation of a kidney is largely in the experimental stage.

Pyelitis is an infection of the pelvis of the kidney, that is to say, of the part where the ureter leaves the kidney. It is usually caused by the bacillus coli, which is normally present in the body, or by the streptococcus. These germs may reach the ureter through the blood-stream or may pass upwards from the bladder. Obstruction anywhere in the urinary tract which causes the urine to stagnate is liable to cause pyelitis. Symptoms come on suddenly, with high fever, pain in the loin (the infection is usually on one side only, and is commoner in women), and pain in the abdomen. When urine is passed there is a burning sensation, and it is passed frequently and in small amounts. On examination, the urine is found to be highly acid and full of bacillus coli or whatever the causative germ may be. Pyelitis is fairly readily treated by the antibiotics or sulpha drugs. Plenty of fluids should be given and the urine made alkaline by administration of alkalis.

Cystitis means inflammation of the bladder, either acute or chronic, and its causes are much the same as in the case of pyelitis. There is pain over the lower abdomen, frequency, and sometimes slight fever. The treatment is as for pyelitis. *Urethritis* is an inflammation of the urethra, with burning pain on passing water and frequency. The most serious cause (although it can usually be easily dealt with now) is gonorrhœa. But non-specific urethritis is common, and in this case various germs or none may bring about pain and frequency; there is often a large neurotic element. Urethritis should be regarded as probably due to gonorrhœa, which has already been discussed elsewhere, when there is a thick, creamy discharge from the penis or discharge in women following sexual intercourse with an infected person.

Kidney stones or Renal calculi sometimes form, and, as in the case of gall-stones, what causes them is not certain. They may be caused by disorders of metabolism—that is, in the inability of the body to deal with calcium, proteins, uric acid, and other products; or by vitamin deficiency obstruction in the urinary tract, and urinary infections. But when a stone or stones are formed various events may occur: thus it may remain in the kidney and cause no symptoms; or it may cause repeated attacks of pain, infection, and blood in the urine (hæmaturia); or it may completely block the passage of urine from the kidney to such a degree that it degenerates and becomes useless; or, lastly, it may pass into the ureter, and when this occurs very severe pain, known as *renal colic*, will occur. A stone passing down the ureter into the bladder may become stuck in the urethra, although this is uncommon, since a stone small enough to get down the ureters is likely to be capable of manœuvring through the rest of the tract. In fact, about 80–90 per cent. of stones are passed spontaneously. Stones not passed spontaneously may have to be removed by operation, but whether this is undertaken or not depends on various factors, such as the general health of the patient, the amount of trouble caused by the stone, and the health of the other kidney —for it is dangerous to operate on one kidney unless one is sure that the other is functioning efficiently.

If a stone blocks the passage of urine on one side for any length of time *hydronephrosis* may result, in which the part where the ureter enters the kidney swells with the retained urine. Ultimately much of the kidney may be destroyed by the back-pressure. The same effect may be produced by kinking of the ureter or anything else which causes obstruction. Sometimes children are born with hydronephrosis, and when the dilation is due to kinking of the tube the condition may be intermittent, with attacks of renal colic during which only small amounts of urine are passed; this is followed with relief and the passage of large quantities.

Tumours and Cysts. The kidney may also be the site of tumours and cysts which produce pain in the loins, sometimes a lump over the kidney which can be felt, and blood in the urine. Cancer of the bladder is a serious condition in which the bladder may have to be removed, so the urinary flow has then to be directed elsewhere. Either the ureters are brought out on to the skin surface, a procedure known as *cutaneous ureterostomy*, or they are implanted in the large bowel, so that the urine flows out with the fæces. This is described as *uretero-colostomy*.

There may also be benign tumours of the bladd or *papillomas*, which are soft and bleed easil a great deal of blood is passed, but there is usual little or no pain. In this, and similar, diseas of the bladder examination of the inside of t organ is carried out by means of a cystoscope, thin tube which is passed up the urethra and h a small electric light at the end which enables t surgeon to see what is going on. Instrumen may also be passed through the tube, and simp papillomas can be cauterised. Similar instru ments are used in the examination of the stomac (gastroscope) and the bronchial tubes (bronch scope). When some obstruction in the outlet the bladder or in the urethra occurs the bladde of course, fills with urine, which cannot be passe and very painful dilation occurs. In this case a attempt may be made to pass a catheter, a thi rubber tube, into the bladder to relieve t tension, or if this fails a *suprapubic cystomy* performed—an incision is made in the abdome over the bladder and a tube inserted into i through which the urine escapes. This ordinarily a temporary expedient, and later whe the patient's health has improved an attempt w be made to remove the cause of obstruction. T most common cause of such obstruction *enlargement of the prostate gland* at the base of t bladder, which surrounds this area and t beginning of the ureter. About 40 per cent. men over sixty have some degree of obstructio due to this cause, and about 20 per cent. of the require operation. The gland is about the size a walnut, and, as we have seen, its function is supply part of the fluid which makes up the seme the male sex secretion. Enlargement of the pro tate may be benign or malignant, and, althou nobody knows just why, such benign enlargeme tends to occur in most men in later life. The may be no symptoms, but characteristically the is frequency during the day and the need to g up at night to pass water. The flow of uri being impeded by constriction of the urethr the passage is less forceful than normal, and the is a tendency for dribbling to occur. If t obstruction is severe and not relieved the bac pressure may be transmitted to the ureters a kidneys, resulting finally in kidney failure a uræmia. The prostate, except in cases of ve mild enlargement, has to be removed eith through the abdomen or through the perineu (the part of the body lying between the sex orga and the anus). Sometimes, in less serious case it is possible without an incision to cut away t obstructing part by an electrocautery inserted, is a cystoscope, through the urethra. Prostate tomy was once a serious operation, all the mo so because the patient was usually elderly and n in good condition, but new techniques and t use of antibiotics have greatly improved t outlook.

Cancer of the Prostate is always serious, but discovered in time it can be operated on succes fully. The gland, of course, has to be complete removed; in inoperable cases, or in patients un to stand operation, the tumour may be treated b means of female sex hormones, which cause it shrink and may prolong life by some years.

DISEASES OF THE NERVOUS SYSTEM.

The brain and nervous system are like a tel phone exchange which sends out and receiv messages from the rest of the body. Essentiall it consists of two levels, the lower centres, whe primitive emotions are felt, the viscera controlle and simple actions initiated, and the true brai which holds the lower centres under contro When, for example, one is pricked with a pin, message is passed up the nerves (the senso nerves or nerves of feeling) to the lower centr in the spinal cord, which return a messa through the motor nerves (the nerves dealing wi movement), causing the hand to jerk away. A this takes place without any conscious inte ference, and can, in fact, happen even when t true brain has been removed. It is, of cours possible for the movement which jerks the ha away to be inhibited, because in this case t brain intervenes; all mental life is a consta interaction between the lower and higher centr

n we become angry, for instance, the anger
nates in the lower centres, but may be in-
ed by the higher ones. To some extent, the
er correspond to what a psychologist would
ibe as the unconscious mind, the latter to
onscious mind.

e nervous system is made up of nerve cells
n are smaller than the head of a pin but end

These fibres form the nerves of the body.
they end in the motor nerves, which bring
t muscular movement, or in the skin, where
are separate nerve-endings dealing with
ure, heat, cold, pain, and so on. It used to
pposed that there were areas in the brain
ng with such mental faculties as acquisitive-
conscientiousness, and other abilities; but
is known to be quite untrue. There are,
d, areas dealing with movement, sight,
ng, speech, feeling, and thought, but cer-
y none dealing specifically with the more
lex mental faculties. Nor is it correct to
ose that each nerve cell carries some particular
ght or feeling; for it appears that thinking
eeling are represented by nervous circuits in
rain and are not isolated in any special area.
large parts of the brain can be removed
out interfering with mental activity.

e most primitive part of the nervous system
e autonomic nervous system, which has its
in" in the hypothalamus at the base of the
brain. It is divided into two parts: the
athetic nervous system, which supplies the
ra with impulses which prepare the body for
or fight (causing the heart to beat faster,
uscles to become congested with blood, the
to become pale, and the blood-sugar to rise
t the intestines become less active), and the
ympathetic nervous system, which, in
al, produces relaxation. When the para-
athetic system acts, the heart beats more
y, the skin becomes flushed, the intestines
food, and the body is prepared for rest.
, as we have seen, the lower centres are the
es controlling both emotion and the internal
s, it is clear that emotional states will
nce the action of the body. This is the
of psychosomatic medicine.

e brain and the spinal cord, which passes
the bony canal within the spine, are covered
he thin layer of tissue known as the meninges
urrounded with cerebro-spinal fluid, which
found in the cavities of the brain known as
cles. A specimen of cerebro-spinal fluid,
S.F., may be removed by pushing a hollow
e between the vertebræ in the lumbar region,
uch specimens can give a great deal of
nation about what is going on in the nervous
n.

e diseases of the nervous system can be
ed into various groups: there are those due
uries, such as fractures of the skull or divided
s; the infectious diseases, most of which
been discussed already; the diseases due to
rrhage or embolism; tumours; and, perhaps
ggest group, the degenerative diseases.

blood-vessels of the brain are one of the
on sites of *aneurisms*, bulges like small
s, often at the base of the brain, caused by
ess of the vessel wall. This is sometimes
sult of arteriosclerosis, syphilitis infection,
ury, but perhaps most often the aneurisms
ngenital—*i.e.*, the individual is born with
There are usually no symptoms, although
aneurism is large enough it may press upon
structures and cause symptoms recognisable
e specialist. In most cases the diagnosis is
ent only when the aneurism, as may occur,
es. When this happens the symptoms are
of brain hæmorrhage. There is severe
che, vomiting, and loss of consciousness,
tient breathes heavily, and when the doctor

on, in the few cases in which symptoms
before hæmorrhage, the presence of an
sm is suspected, this may be confirmed by
Since soft tissues are not seen in X-ray
es, it is necessary (for example, in the gall-bladder, the kidneys, the bronchi, or the blood-vessels of the brain) to inject some radio-opaque substance which outlines them. In the brain this is known as arteriography, and when by this means aneurisms or other abnormalities are found surgery is sometimes possible. Hæmorrhage into the brain substance produces what is generally known as a *stroke*. The artery affected is usually the middle cerebral, when in later adult life it has been strained and weakened by high blood-pressure or arteriosclerosis. It can, however, be caused by bleeding into a tumour, or in children by birth injuries. Hæmorrhages may also result in the small veins from the strain of coughing in whooping cough.

A stroke comes on suddenly, and the patient is flushed with a bluish tinge. He breathes heavily and, as he breathes, the cheek on the affected side may be blown in and out. Since the left side of the brain supplies the right side of the body, and *vice versa*, the side of the body on the opposite side from the hæmorrhage is paralysed. The limbs and face right down the affected area are flaccid and useless, but if the patient survives they will at a later stage become spastic. There are, therefore, two types of paralysis: flaccid and spastic. In the first, the limb is incapable of movement, and when lifted it falls back like a dead weight; there are no reflexes, so that when the knee-cap is tapped to elicit the knee-jerk there is no response. Flaccid paralysis is typical of injury to the lower parts of the nervous system, and it means that no impulses are getting through. Spastic paralysis, on the contrary, is characterised by rigidity of the limb, overactive reflexes, and even when movement is possible it is out of control. This, in fact, is what has occurred; for spastic paralysis indicates that, although the lower nerves are undamaged, the controlling centre in the brain has been affected.

If the patient survives, there may be varying degrees of improvement in the paralysis, which is always at its greatest in the beginning.

When such an emergency occurs it is best to leave the patient where he is, keep him warm, take out his dentures if any, call the doctor, and on no account to give him any fluids or alcohol. No patient in coma should ever have fluids poured down his throat. Other causes of coma are diabetes, alcohol, uræmia, acute hypertensive (high blood-pressure) attacks, and thrombosis or embolism.

In thrombosis and embolism a similar picture to that of hæmorrhage occurs. Embolism comes on suddenly like a hæmorrhage, but in thrombosis or clotting the onset may be more gradual, with premonitory symptoms of headache, giddiness, and numbness or pins and needles in the limbs. There may be difficulty in speaking.

Tumours and Abscesses. The brain is soft, greyish white in colour, and from the upper surface closely resembles a huge walnut in that it has two sides joined across the middle by a smaller part known, in the brain, as the corpus callosum. It resembles a walnut, too, in that its surface is crumpled up into convolutions. Investigation of the brain has become more and more refined in recent years, the following being some of the techniques employed:

(1) Straight X-rays.

(2) Arteriograms, which have already been described.

(3) Encephalograms or ventriculograms, in which some of the fluid, the C.S.F. surrounding the brain or in the cavities known as ventricles within the brain substance, is removed and replaced by gas. The gas may be helium or oxygen, and it has the effect in an X-ray picture of outlining the brain and ventricles so that any distortion of shape due to a tumour or abscess is outlined.

(4) Electroencephalograms are pictures made of the electrical brain waves produced by the brain, just as the electrocardiograph takes pictures of the similar waves produced by the heart. Electrodes attached to the scalp may show abnormal waves over the site of a tumour or abscess.

(5) Still more recently, radioisotopes have been used to locate tumours, since radio-

active substance become concentrated in the area of the abnormal tissues.

The main symptoms of brain tumour are severe headache, vomiting, and disturbances of vision; such symptoms must be referred to a doctor at once. The pulse-rate is usually slow. All these symptoms are caused by increasing pressure within the brain because of the space taken up by the tumour.

The popular belief that a brain tumour is tantamount to a death warrant is simply untrue; for at least 80–90 per cent. of cases recover. The main types of tumour are meningiomas (*i.e.*, tumours of the brain coverings or meninges); tumours of the nerve fibres within the brain or neurofibromas; tumours of the pituitary gland; and gliomas, which are tumours of the background substance. The outlook for all of these is good, except in the case of the glioma, which is a type of tumour which tends to infiltrate into the rest of the brain fairly rapidly. It is not localised, and therefore complete removal is not always possible.

Brain abscesses may be spread from the bloodstream in people with bronchiectasis, osteomyelitis, infected sinuses, or chronic ear disease. The symptoms are similar to those of tumour, but there is also fever and drowsiness.

Aphasia is a disturbance of the ability to speak, write, or to understand spoken or written words. It is usually due to a tumour, abscess, thrombosis, or embolism of the speech area in the brain. In motor aphasia the muscles of speech are normal, but the patient is unable to speak intelligibly. In nominal aphasia the patient cannot name objects, which he nevertheless is able to recognise. In agraphia the patient cannot write, although his muscles are normal. In word-blindness and word-deafness the patient cannot understand written or spoken words respectively. Treatment depends upon the cause, but in hopeful cases re-education is sometimes possible.

Headaches. This seems a convenient point to say something about headache, which must surely be one of the commonest symptoms suffered by the human race. We shall begin by noting that at least 90 per cent. of all headaches are nervous in origin or the result of such other minor troubles as gastric upset. It is doubtful whether headache is as frequently brought about by eye-strain as is often supposed, but there is certainly no harm in having one's eyes tested if frequent headaches are present.

A doctor will first try to distinguish between headaches due to mental causes and those due to organic or physical ones. When the cause is physical the headache is often very severe, usually located sharply in one area (for example, on one side of the head), and it is likely to be accompanied by other symptoms, such as vomiting and eye-disturbances. The person with this type of pain often tries to minimise the pain he suffers, but his behaviour—for example, his obvious fear of moving his head—belies him. The neurotic person, on the other hand, suffers from headaches which are "terrible," "awful," "unbearable," vague in their location (they are "all over"), and, if they are accompanied by other nervous symptoms, the diagnosis is clear. Apart from the neurotic type, headaches are caused by migraine, increased pressure within the skull, as in brain tumour or abscess, sinus disease, and eye diseases. Treatment obviously depends on the cause, and the sensible thing to do is to go to a doctor, believe what he says, and take his advice. Neurotic headaches may be dealt with by investigation of the sources of worry, frustration, and so on which cause the pain, or by taking aspirin or other pain-relieving drugs. (Pain, in fact, is one of the very few things aspirin is good for, and as has already been said elsewhere, those who believe that it is good for "nerves," insomnia, and all the various conditions which make aspirin an almost universal cure in the minds of many, are deluding themselves.)

Migraine is a disorder which many claim to possess and not so many really do; if all the people who claim this dubious honour—often those who have little better to do than be bored with themselves—if all these were put end to en or even stood upright in a line, they would surel encircle the Earth. True migraine, however, is very clear-cut disease, and happens in a ver definite type of person. The owner of th migraine tends to be a highly intelligent and co scientious—even over-conscientious—individu (not at all like Mrs. Jones, who says she suffe from it and could by no stretch of the imaginatio be described either as intelligent or over-co scientious). The headaches are severe, usually o one side of the head only, occur in periodic attack and are not, like the headaches suffered by Mr Jones, "there all the time." Vision is affecte so that there may be hemianopia (*i.e.*, half-vision flashes of light before the eyes, and the so-calle fortification spectra (*i.e.*, zig-zag patterns in th field of vision). The pain is often prostratin and is usually followed by attacks of vomitin Migraine is a mystery disease which apparentl has something to do with the personality, wit emotional stresses, and conceivably in some case with allergy; the actual pain appears to caused by spasm of the blood-vessels in the brai The usual treatment is with tablets of ergotami (Fermergin), but other remedies are also helpf in different cases.

There are a number of other nervous disease the cause of which remains a mystery, and these we shall mention epilepsy, chorea, and pi disease.

Epilepsy is a symptom, not a disease, which common at all ages but especially children. has been attributed to St. Paul, Julius Caesa Napoleon, and (with more justice perhaps) Dostoievsky. Many varieties of attack occ often in the same patient, the commonest a best known being the *grand mal* or major seizur In this the patient falls down unconscious a rigid and the jaw is clenched, so that there danger of the tongue being bitten. This so-calle tonic phase is followed, within a minute or by a clonic phase in which the limbs contra rhythmically. The attack ends with the patie going limp and gradually recovering consciousne a process which may take up to an hour. Occa ionally the patient has a brief warning, most oft an indescribable feeling in the stomach. The are two common forms of minor seizure, o occurring mainly in children and the other mo often in adults. The common minor attacks children are often called *petit mal* or *absence*, whi well describes the instantaneous and brief loss consciousness often unaccompanied by a change in posture. Recovery is equally instanta eous. On the other hand, in the other forms epilepsy which arise from various parts of t brain, but especially from the lobe under t temporal region, there is often a warning simil to that which may precede a major seizure. these cases the patient shows only confusion, definite loss of posture, but automatic activi such as fumbling with buttons, muttering, a grimacing. Following these attacks there may a quite prolonged period of confusion in whi the patient may wander away and occasional may be violent. Criminal acts are very rare carried out in this state.

A large number of people have had one or tw fits in their lives, particularly at times of physic or psychological stress. "Fever" or "Febrile convulsions (often called teething fits in the pa are extremely common in young children and a often thought of as something different fro epilepsy since the attacks rarely continue in lat years. This form of epilepsy and some cases *petit mal* are the only forms in which heredita factors are important in the causation, and the are the least serious forms of epilepsy. They a very rarely associated with serious physical psychological disturbances. Most other forms epilepsy are due to a scar or other area of bra damage. It is a proportion of these cases whi develop the psychological disturbances that a occasionally very serious.

Not every patient who has had one or two f need necessarily take regular anticonvulsa drugs; that is drugs which damp down t abnormal excessive activity of the brain that lea to the attacks. Many drugs are available of whi the most important are phenobarbitone, phen toin, succinimides, and troxidones, the last tw

g effective only against minor seizures.
ch one to use and whether to use one at all is,
urse, quite a complicated judgment, and must
eft to the doctor. Epileptics often find it
ult to get work because of the reluctance of
loyers to take on someone who may be more
e to accidents and whose fits may distress
r workers. Obviously there are some jobs
h epileptics should not do because of the dan-
nvolved, (from, for example, moving machin-
and they should not drive a car. A few
are so severe that work is almost impossible,
employers have a duty whenever possible to
loy these people whose mental health may
r greatly if they are made to feel outcasts
who ordinarily are as efficient, or even more
as the next man. It is also hoped that
oyees will become less prejudiced about
psy as the general public become less ignorant
t medical matters. In this way epileptics
come to be accepted in all those kinds of
oyment for which they are well suited. If
of the famous men who have suffered from
disease had had to rely on the charity of some
oyers today the world would have been much
poorer, although possibly we could have
aged without the generals.

e British Epilepsy Association exists to
guidance to people with epilepsy, their
lies, and friends. It provides a full-time
re service and a chain of social clubs. It is
erned by means of books, films, courses, and
res to make known the true facts about
psy. It seeks to share its knowledge with
nisations in other countries. Its offices are
3–6 Alfred Place, London, W.C.1. Tel.
2704/5.

orea, or St. Vitus' Dance, is connected in
way with rheumatism, especially with
natic fever. It is much less common than
erly, and is also known as Sydenham's chorea,
the English physician who first described it
o distinguish it from Huntington's chorea, a
us hereditary and incurable degenerative
se which leads to progressive mental deteriora-
Fortunately, Huntington's chorea is rather
The patient with Sydenham's chorea is a
most often a girl, and one who has been
r delicate and nervous. She shows an
lity to keep still and makes purposeless
ments, such as writhing and twitching of the
and grimaces of the face. The speech may
ected, and the muscular inco-ordination may
pronounced that dishes or other objects fall
the hands when lifted. The treatment for
a is that for acute rheumatism with the
ion of sedatives. The heart may be affected.

nk Disease is a disease of young children
een the ages of six months and three years.
it should be included here is not certain: for
use is unknown, and the theories to explain
igin range from the supposition that it is a
in-deficiency disorder, an infection, or the
of poisoning by mercury in teething
ers, to the more probable theory that it is a
otor disorder like chilblains brought about
e nerves which control the diameter of the
es. (Here it should be said that "teething
ers," whether or not they play any part in
g this disease, should never be used any-
since in the first place—doubtless to the
indignation of mothers who, of course,
s know best—one must say that it is
nely uncertain whether the many disturb-
allegedly due to teething have anything
with teeth at all, and secondly, that whether
teething causes anything, it is certain that
umerous powders available in the shops can
othing about it.) Pink disease was first
bed in Australia in 1914, and the general
e is that of a child in acute misery with
g or burning of the hands and feet, which are
n and pink in appearance. Sometimes the
ears, and nose are affected, there is loss of
ite, sweating, insomnia, and thirst. The
ent of the condition, which may last many
s but with an ultimately good outlook, is
on of the B vitamins, especially B12, rest,
edatives.

Angio-neurotic œdema. Another mysterious disease, common to both children and adults, and mentioned here because it, too, seems to be caused by malfunctioning of the nerves controlling the blood-vessels, is angio-neurotic œdema in which attacks of œdema (swelling) occur in various parts of the body, but are most apparent in the face. Undoubtedly allergy to various foodstuffs can play some part, but emotional factors are at least equally important. Very frequently, without any warning at all—but often after an emotional outburst—the face within a short time swells so that the patient is almost literally unrecognisable. Sometimes the swelling is so severe that breathing is endangered by œdema of the glottis, the entry to the windpipe. An immediate injection of adrenalin usually starts to clear up the condition, and for later use the antihistamine drugs have proved helpful.

THE DEGENERATIVE DISEASES.

There are very many conditions coming into this category, and they are given different names according to the parts of the nervous system affected. However, they all have this in common, that they are the result of a degeneration of groups of nerve cells, usually for no known reason, and, since nerve cells once destroyed can never regenerate, the diseases are usually irreversible and progressive. In a few cases, however, they can be arrested or simply die out.

It would be impossible to deal even briefly with all these diseases, so here only a few of the more common ones will be discussed. The ones we shall mention are: muscular atrophy, amyotrophic lateral sclerosis, disseminated sclerosis, syringomyelia, and subacute combined degeneration.

Muscular atrophy is, in fact, a whole group of diseases in which there is some damage to the lower parts of the nervous system, usually in the nerve cells at the point where they leave the spinal cord. The common type, *progressive muscular atrophy*, occurs in middle age or over, and the patient begins to note wasting of the muscles in first one hand and then the other. Ultimately, the hand becomes claw-shaped, and some wasting may spread up the forearm. It may finally spread up to the base of the brain, with fatal results. There is no known cure. In children a similar condition is *peroneal muscular atrophy*, in which degeneration of the nerve cells in the spinal cord leads to wasting both of the hands and legs. In this case the disease may stop of itself after several years.

Amyotrophic lateral sclerosis affects both the lower and higher nerve cells. There is wasting of the hands and arms, with increasing weakness, and the legs show a spastic type of paralysis, *i.e.*, they do not waste, but the muscles are in varying degrees of spasm and the knee-jerk and other reflexes are increased. The disease has been treated with concentrated vitamin E, but the results are uncertain. It should be noted that to say that a disease is incurable is not at all the same thing as saying that the patient is going to die from it. Some of these diseases progress very slowly, or may stop of themselves, and any disease process tends to go slower as one gets older. For example, many old people with cancer die of old age long before they are in danger of dying from the disease.

Disseminated sclerosis—sclerosis means hardening of the affected parts of the nervous system—is a progressive condition which goes on with periodic intermissions of improvement. Often the first symptom is double vision or sudden weakness in a limb, but the later symptoms are largely those resulting from loss of muscular co-ordination; thus, when the patient is asked to shut the eyes, stretch out the arm at right-angles to the body and then touch the tip of his nose, he manages the first part of the movement fairly adequately, but as the finger nears the nose it starts to wobble and fails to reach its goal. There is thus some loss of sense of position and difficulty in carrying out such actions as drinking tea from a cup. Another typical symptom is nystagmus, in which, when he is asked to look to one side, the patient's eyes jerk back and forth (this condition is, of course, also a feature of so-called "miner's nystagmus," which appears to have a large psychological element and certainly has nothing to do with disseminated sclerosis). In later stages the spinal cord becomes affected and there are varying degrees of paralysis in the lower half of the body so that the legs are useless and there is loss of control of bladder and bowels. Thus, although disseminated sclerosis is not by itself a fatal disease, it does result in the long run in the patient becoming increasingly bed-ridden. Examination of the nervous system reveals that the covering of the nerve fibres—which have a sort of insulating layer much the same as in the case of electric wires—has been damaged and the underlying fibres have degenerated themselves. Where this damage occurs, and this appears to be completely fortuitous, determines the nature of the symptoms and where they occur. Many treatments have been tried, but their number only emphasises how little we know. The disease may be the result of inborn weakness in the fibres, of allergy, or of a virus infection with a so far undiscovered virus, but since it occurs in young adults in the prime of their life it is a particularly tragic disorder. Strangely enough, it is confined almost entirely to Europeans, and is rare elsewhere in the world.

Syringomyelia, another degenerative disease, is caused by the formation of small cavities in the upper parts of the spinal cord in the neck and chest regions. These cavities become surrounded with scar tissue, and hence interfere with nerve impulses passing down the areas where they occur. The patient may be any age between ten and thirty, and suffers from both sensory and motor symptoms. There is wasting of the muscles of the hand, and sometimes of the arm and shoulder, and specially typical is loss of the sense of pain with retention of the sense of touch. Because of this, the patient may burn or cut his fingers without noticing anything. The disease is slowly progressive over a long period of time, and there is no known effective treatment.

One of the few degenerative diseases which can be treated is *subacute combined degeneration*, which is invariably associated with pernicious anæmia. A middle-aged patient notices numbness, pins and needles, and so-called lightning pains in the fingers and toes and later in the limbs. The muscles are weak, and the tongue is smooth and glossy. On examination, the symptoms of pernicious anæmia are found. Treatment for the anæmia puts a stop to the disease, although damage already done may remain.

INFLAMMATORY DISEASES.

These are those, such as shingles or neuritis, which may be due, as is shingles, to virus infection, or to various causes, as is neuritis. The virus causing *shingles* is apparently the same as that causing chickenpox. Shingles, or to give it its proper title *herpes zoster* (it must not be confused with *herpes labialis* or cold sore of the lips, with which it has no connection whatever), shows itself in the form of a band of pain surrounding the upper abdomen or chest, which is then followed by an eruption with blisters in the affected area. There is no specific treatment; aspirin may be given for the pain and the reuption painted collodion or "New Skin." Ordinarily the condition clears up fairly quickly, but the pain may persist for a long time. Injections of vitamin B12 are sometimes helpful.

The word "neuritis," meaning inflammation of a nerve, covers many different types of illness: polyneuritis, simple neuritis, neuralgia, sciatica, prolapsed vertebral disc, and other conditions. All they have in common is nerve pain; for, as in the case of "colds," one cannot assume that because a condition has one name it represents one disease or has even one cause.

Multiple, peripheral, or polyneuritis is, as the name indicates, a condition in which numerous of the peripheral nerves, mainly in the limbs, are affected. The symptoms will vary according whether motor or sensory nerves are attacke The causes are various: poisons, such as lea arsenic, or alcohol; bacterial poisons, such those of diphtheria, typhoid, or gonorrhœa vitamin deficiencies, as in beri-beri; and, finall diseases of metabolism, such as diabetes. Rarel an infection known as acute infective polyneurit causes the symptoms. The parts affecte depend to some extent on the cause. Thu alcohol brings about, when taken in excess, pa in the calves and foot-drop (*i.e.*, the foot han down and cannot be raised to its normal position neuritis due to diabetes and arsenic shows simil symptoms, whereas in lead poisoning not only t foot but also the wrist may be affected. Dipl theria tends to attack the palate and the eye causing difficulty in swallowing and in vision.

The ordinary type of neuritis, however, localised—and here it should be said that man pains described as neuritic are nothing of the sor being probably caused by fibrositis or muscle an joint disorders. Typical of localised neuritis *Bell's palsy*, neuritis of the facial nerve, in whic one side of the face is paralysed so that the eye the affected side will not shut, and the mout droops down. Asked to whistle or blow out h cheeks, the patient with facial paralysis is unab to do so. The usual cause of Bell's palsy is cold— for example, it is common to find that the patie has been driving with the car window open in co weather. But facial paralysis may also be cause by infection in the middle ear. Most cases cle up in a fairly short time, but in a few instances t palsy is permanent. There is very little eviden that the treatments usually employed, such electrical stimulation, have any effect, but i jections of concentrated vitamins B may be use

Other familiar types of neuritis are *sciati* and neuritis in the arm. They can be cause by fractures, or pressure from tumours, or t callus (excess bone) in badly healed fracture cold, too, is said to be a factor, and then there always "idiopathic neuritis"—which, in everyda language, means that one does not know t cause. Most cases, regrettably, are idiopathi In sciatica, we have a condition which is not disease but rather a symptom. The familiar pa down the back of the leg may be caused by alcoh rheumatism, diabetes, tumour, fibrositis, "slipp disc," arthritis of the hip joint, dislocated sacr iliac joint, infection such as tonsillitis, and on. Treatment depends on the cause, whi frequently is never found.

Prolapsed Intervertebral disc is a popular disea in these days. It causes a sciatica-like type pain, and is brought about by the bulging of intervertebral disc (the shock-absorbers, which between the vertebræ of the spinal column) in the area where it can press upon the nerve roo Treatment is first by rest and pain-relieving drug if this is not enough laminectomy is performed a the protruding part of the disc removed.

Paralysis agitans or *Parkinson's disease* ma result in young adults following an attack encephalitis, or in older people, in whom the part the brain concerned simply deteriorates. T face becomes expressionless, the movements st and slow, the gait shows a shuffling tendency, which the patient bends forward and seems to running to catch up with himself. There tremor of the fingers and the so-called "p rolling" movements, in which the thumb a fingers are constantly moving against each oth Treatment is by drugs, such as hyoscine or mo modern proprietary ones; in some cases surgi operation has been used with varying degrees success. The disease is also known as "shaki palsy."

MENTAL DISEASES.

Psychosis.

Mental diseases are divided into psycho (*i.e.*, insanity) and neuroses (*i.e.*, what is ordinar known as "nerves"). Psychoses, in their tu are divided into organic and functional—those d to physical disease and those in which no physi

has been discovered. In point of fact, the
ction into organic and functional is rather
ingless; for if we accept the modern view of
osomatic medicine which regards the body
nind as a single unit it is clear that organic
se brings out psychological defects which
already there and that functional disease
in the final analysis, be the result of physico-
ical causes, even if this is brought about by
al stress.

anic disease results from poisoning of the
us system by such poisons as alcohol, carbon
xide, or lead; vitamin deficiencies, as in
ra; infections such as syphilis; and
eration of the brain, either primary or as a
of poor blood supply. In all cases its main
toms are confusion, signs of other disease,
oss of memory. Alcohol leads to various
tions: in *delirium tremens* heavy bouts of
ing end in delirium ("D.T.s"), confusion,
cination—although not necessarily of pink
ants or rats. It is a serious disease, but the
ok is much improved since it was discovered
njections of concentrated vitamins B and C
form of "Parentrovite" can help. In more
ic cases *Korsakov's syndrome* manifests
in the form of mental deterioration and
ry defects. There can be little doubt that
usly existing mental instability is a pre-
sing factor in these conditions. The same
be said of *general paralysis of the insane* or
., and in this case the immediate cause is
itic infection of the nervous system. Never-

ent by insulin and the new tranquillising
has revolutionised the outlook in this
edly serious disease. Indeed, some cases of
sis are more easily treated than neurotic
s, since the former respond to physical
methods, whereas the latter may require fairly prolonged psychotherapy (psychological treatment) and are less responsive to drugs.

In cases which do not respond to other methods, the brain operation known as *leucotomy* may be performed. Leucotomy is also performed to alleviate intractable pain, as in incurable cancer, but some of the ataraxic drugs (tranquillisers) are probably equally useful for this purpose. Leucotomy involves the severing of the connecting nerve fibres between certain areas of the brain, and the results are often favourable, but in fact the operation should be performed only in cases where the outlook is otherwise very poor; chronic severe neuroses, frequent attacks of manic depressive psychosis, severe chronic depression, and schizophrenia which has not responded to other forms of treatment. The operation reduces anxiety, fear, aggressiveness, and agitation, but may result in the less-desirable symptoms of apathy, impaired judgment, lack of self-control, and loss of initiative.

Schizophrenia developing in later life is likely to be less dramatic in origin, and the delusions tend to be more systematised—that is, they take a persistent form, which does not change from day to day. This type of the disease is known as *paraphrenia*. In those beyond middle age the rare but dangerous condition described as *paranoia* may develop in which there are no hallucinations and the only symptom is a completely systematised collection of persecutory delusions, which on recital may sound entirely convincing even to the ordinary doctor. Such people are dangerous precisely because they are so plausible, and they fill the ranks of the litigious, the troublemakers, and the political and religious eccentrics. One such patient known to the writer spent his life in a mental hospital from which he had parole, employing this to form a society propagating highly eccentric sexual and political beliefs. It says little for the intelligence of the general population that his meetings were invariably crowded out (although, of course, when one reads of the people who apparently believe that the various fictitious families on radio or television—the Groves, the Archers, and the like—really exist, one need not be surprised at such examples of communal dottiness, even if one may despair of democracy).

Manic-depressive insanity is characterised by mood swings in which the emotions alternate between wild elation without obvious cause and equally causeless depression. However, the picture is not quite as simple as this; for phases of mania or excitement may occur without depression obviously following, or there may be a single attack of depression with no manic phases. The disease may be absolutely incapacitating, or there may be periods of relative normality; typically, then, manic-depressive insanity is a disease of alternating moods. The depression responds to electroconvulsive therapy or E.C.T., but mania is less responsive to treatment. However, it ordinarily remits of itself. Sometimes in middle age *involutional depression* occurs, and this in the vast majority of cases is cured by E.C.T. As in the case of schizophrenia drugs are increasingly used for depression. Chlorpromazine in the former case and in depression Nardil or Tofranil, etc. The ever-present risk in depression is suicide.

Neurosis.

The main neuroses are anxiety neurosis, hysteria, and obsessional neurosis. *Anxiety neurosis* is an illness in which the main symptom (as the name implies) is anxiety. There is fear which rationally the patient knows to be groundless; there may be anxiety attacks, in which the heart pounds, the patient feels he is going mad, is unable to sleep, and worries "for no reason at all." In hysteria, anxiety is largely absent, but there may be apparently physical symptoms ranging from paralysis of the limbs to blindness, deafness, inability to write, and lapses of memory (the so-called hysterical fugues or loss of memory). Typical of *hysteria* is the fact that the patient is less worried by his symptoms than would be expected from their apparent seriousness; this is what the early psychiatrists described as "la belle indifférence." The reason for the indifference is simple—it is that the paralysed individual *wants* to be paralysed, the blind *want* to be blind, the deaf to be deaf (there are none so blind—or deaf—as those who don't want to see, or hear), and the person who doesn't want to write conveniently finds that he cannot.

Generally speaking, neurotic people are suffering from a failure to face up to reality. They are not physically ill and are largely the end result of a faulty upbringing. It is wrong to suppose that the only bad families are those in which the children are ill-treated; much the worst ones are those in which children are spoilt, the parents possessive, and the wrong kind of love is dispensed. Neuroses are the result of a conflict between primitive desires and what the individual has been brought up to believe he should be. For example, before an examination a student may develop a nervous breakdown because he fears failure when he has been brought up to expect success. The excuse, of course, is "overwork"—an entirely non-existent condition. With his breakdown he solves his problem, he avoids the fear of failing and preserves his self-respect: he has been ill. Similarly, the soldier with "shell shock" (another non-existent condition) has a conflict between his sense of duty and his fear of death, which again is solved by becoming ill. Or, to take a final example, a woman feels the duty to look after her ageing mother. But she also wants to get married. So she unconsciously develops a neurosis which says, in effect, "I should like to do my duty in looking after my mother, but unfortunately I am unable to." There is an unconscious rebellion on the part of the mind.

Neurosis, in effect, is not a disease—it is a self-inflicted injury, a form of maladaptation to life. The neurotic, no matter how much he suffers, does not want to get well; he has found some way of getting along, even if a foolish way, and he intends to keep it. Often his symptoms are the sort of excuse that say: "If only I wasn't ill what wouldn't I be able to do!" The neurotic is a person who is different and is afraid to be himself; his problem is a conflict between being "ordinary," "like other people," and being what he was supposed to be. You will find some further references to neurosis in Section Q, Part II.

Obsessional Neurosis is a more severe type of neurotic illness; for although in anxiety neurosis we find such symptoms as phobias—irrational fears of open spaces, closed spaces, animals, and so on—obsessional states are characterised by compulsive feelings that certain acts must be performed or certain thoughts thought. In a mild form we all have obsessions: we feel that we must walk on the spaces between paving-stones, that we must touch lamp-posts, and so on. But when this type of compulsion gets to the stage when we must go back several times to make sure the lights have been put out, when we feel the need to wash our hands every few minutes, become obsessed with numbers on cars or dates on coins, then it becomes a nuisance and requires treatment. Usually the treatment is psychotherapy—whether psychoanalysis according to the method of Freud or shorter methods—and, in serious cases, physical methods such as L.S.D. (lysergic acid) or leucotomy. The obsessional neurotic is a person who feels that life must be controlled; he is "a creature who moves in predestinate grooves—he's not even a bus but a tram." His symptoms are an attempt to devise self-imposed rules which will control the unconscious desires of which he is so afraid.

Neurasthenia is an entirely imaginary condition allegedly due to exhaustion of the nervous system. Since no such condition exists, we need not bother with it. Neuroses cannot be treated by feeding the nerves (which are perfectly normal). They can be helped by such things as sedatives, but not cured. *Neurosis has nothing at all to do with disease of the physical nerves, so nerve tonics do not
exist, and anyone who asserts that they do i*
humbug. Glycerophosphates and the usual co
tents of tonics are excreted almost as soon as th
are taken in, and tonic wines are one of the b
ways of becoming an alcoholic. The one reas
for not taking alcohol is when one craves it, a

several dust-carts to carry away the store
empty bottles left behind when she died.

Psychopathic Personality is the term given
anyone who has different standards of behavi
from those generally accepted by society. So
of these unfortunates may be *inadequate*, that is
say, although perfectly intelligent, unable to e
their own living. Others are the *creative* peo
who, as in the case of Van Gogh, did many ecc
tric things but also many productive thing
Van Gogh was gifted, or cursed, with an inte
sensitivity. Lastly, there are those who ha
what others regard as peculiar sexual habits.
the first two classes nothing more need be sa
and all that is necessary is to mention certain
the so-called sexual perversions. (When we say
called the implication is not that none of th
forms of behaviour is perverse but that some
them are carried out by otherwise quite ordina
people.) *Sadism* and *Masochism* refer to, in
first place, pleasure in inflicting pain and, in
second, to receiving pain. The pleasure
sexual, and it is incorrect to talk of cruelty
itself as sadism. Sadism is named after
Marquis de Sade, who suffered from this perv
sion, although he certainly did much less harm
his small way than numerous politicians
generals of our time, and masochism is nam
after the Austrian novelist Sacher-Masoch, w
wrote books which, although unpleasant, were
notably more so than certain Sunday newspap
of today.

Masturbation is sexual self-stimulation. Ne
less to say, it produces no more *physical* ha
than ordinary sexual intercourse—that is to s
none at all, although some people have the stra
belief that every act of intercourse weakens
body and it has even been believed that each
shortens life by a specific length of time. Thi
rather illogical in view of the fact that most of
famous rakes have been noted for their longevi
Masturbation is almost universal in infan
adolescence, or even in later life when other out
are not available. It need only be a matter
concern: (*a*) when it is chosen in preference
normal sexual activity, or (*b*) when it is compuls
and excessive, since then it is a sign, not of sex
desire, but of severe underlying anxiety.

Homosexuality is, as presumably most peo
now know, an attraction between individuals
the same sex. Feminine homosexuality is
illegal in Britain, but male homosexuality
The Wolfenden Report of 1957 takes a mu
more tolerant view of the problem than has b
hitherto current, recommending, in effect, t
homosexual acts between consenting adults sho
be legalised. Homosexuality is, so far as
known, not inherited, and is the result of psyc
logical difficulties in early development; oc
sionally it can be treated by psychotherapy,
it is doubtful whether those "cured" in
way were ever genuine homosexuals. To
humane person it must seem that the Wolfen
Report gives a sensible solution to the proble
for it is difficult to see why the homosexual sho
be treated differently from the heterosex
offender. That is to say, what adults do (w
consent) together is their own business, but
male homosexual who seduces a boy under
should be treated in no way differently from
man who seduces an under-age girl.

All that remains to be said is that many of th
conditions are treatable or, if not treatable so
as cure is concerned, they can at least be relie
The world is full of people who are "differen
there are those who are different in the right w
who should take satisfaction from their achie
ments, and those who are different in the wr
way, who should seek expert advice. Si
psychological treatment is time-consuming, i

th Service, although group treatment has lified the problem. However, any person such difficulties would probably benefit a discussion with his family doctor.

DISEASES OF THE SKIN.

e skin in the course of development before is particularly closely associated with the ous system. It is therefore not surprising so many skin diseases are influenced by ional states. Other causes of skin disease infections, glandular disorders, vitamin iencies, and the numerous conditions for n no cause has been discovered, but which mably are due to metabolic disorders.

e of the commonest skin symptoms is *itching uritus*. It may accompany many different al diseases, for example diabetes and lice. It may also be troublesome during the pause (the change of life in women), in old or in nervous conditions. Sedatives and sex ones sometimes help the itching during the pause, and there are ointments which may eful.

hing in the region of the anus and genital s is relatively common. It may be caused orms, by irritating vaginal discharge, or by in the urine, as in diabetes. The alteration e normal bacteria of the bowel which follows nent with various antibiotics also often s anal pruritus and soreness. In many cases ver the itching has some psychological cause. eatment it is important to avoid ointments creams which contain a local anæsthetic, se these substances can cause severe allergic ons if used for longer than a few days, and thus make the condition much worse. ment with a local corticosteroid application re effective and safer.

asites, such as the *scabies* mite or *lice* can severe and persistent itching. The scabies s very small, and since it burrows under the urface, is unlikely to be seen; it is the cause hing most commonly between the fingers n the front of the wrists. The itching is when the body becomes heated, as in bed. nent consists of painting the body from head t with benzyl benzoate application, followed ext day by a hot bath. Since scabies is cted through close personal contact with an d person it is often desirable for several or mbers of a family to be treated at the same even though only one of them may be d. Lice are specialists, one type of which the scalp, another the body, and a third enital area. Head lice are destroyed by e, body lice by D.D.T (dicophane) powder, enital (pubic) lice by shaving off hair and g. Obviously, the clothes, especially in e of body lice, should be disinfested, either use of D.D.T. or, if this is not available, by a hot iron over the seams, which lice (for nexplicable reason) seem to favour. Apart he discomfort they cause, lice are dangerous ential carriers of typhus fever.

lness, or Alopecia, is a very common condi- is manifested by the extraordinary number parations advertised as curing it. When preparations are offered for the treatment condition it is a fair judgment to assume one of them is likely to be effective. There fact, two types of baldness; one, which is he commoner, is hereditary, and cannot be ced in the slightest by any treatment, the *alopecia areata*, is caused by nervous stress, uld recover in most cases by itself, whether ed a solution of soot and water or the most ive "hair food." There is no such thing air food, any more than there is such a s a nerve food, and although it is probable ir hygiene may delay baldness, it certainly prevent it. All hair tonics and "foods" less, and their uselessness is only equalled r costliness. Those who have lost their d find it growing again after using some tonic are people who have had *alopecia areata* and whose hair would have grown back anyhow. In women the hair often thins out soon after a pregnancy, but a few months later it usually returns to normal.

Seborrhœa is a condition in which there is over-activity of the sebaceous glands. The most usual form it takes is *dandruff*. However, it takes other forms, and those who have dandruff may also have rashes on the face, shoulders, and chest. In these areas there is a patchy, greasy, and often itchy, rash which does not clear up until the primary condition in the scalp is dealt with. The scalp should be washed with one of the modern sulphur-containing shampoos at least twice a week, and the affected parts on the face and chest can be dealt with by the use of a sulphur lotion (*not* on any account by greasy ointments). Seborrhœa is not in itself difficult to treat, but, since the condition depends on over-secretion of sebum, the skin lubricant, treatment may have to be persisted in during the years of early adulthood, when it is most active.

Erythema Intertrigo is, quite simply, the sort of irritation which occurs usually from excessive sweating under the armpits, between the legs, and under the breasts in women. All that need be done is to wash frequently and to dust the affected areas after washing with powder. This is the condition which, in the tropics, is known as "prickly heat" and elswhere as a "sweat rash." In some people *hyperidrosis* or *excessive sweating* is a problem, especially when the sweating is accompanied with body odour—the sort of thing that, according to the advertisements, "even your best friends won't tell you." There is little need for anyone in these days to suffer in this way: for the cosmetic firms have produced many highly efficient deodorants which not only control odour but also control the amount of sweating. Chlorophyll, which has been much advertised as removing odours, is effective when applied directly to surfaces which give off an unpleasant smell. It is however ineffective when taken by mouth, and does not prevent body odours. Stale sweat smells bad because it is decomposed by bacteria, and this type of body odour can be largely prevented by preparations containing a harmless antiseptic such as hexachlorophane and an antiperspirant such as aluminium chloride (see *Which*, February 1960).

Erysipelas is an infection of the skin caused by the hæmolytic streptococcus. It begins as a red, raised area anywhere on the body where the germs have been able to enter through a small crack or cut in the skin. The red area advances and spreads over the body until the disease is got under control. Erysipelas is very infectious, and those who look after the patient should wash their hands throughly after contact. At one time the disease used to spread as an epidemic throughout the hospital wards, but this is very rare nowadays. Treatment is, of course, a matter for the doctor.

Chilblains are common in cold weather, especially in those with poor circulation. Ordinarily they occur in the toes and fingers, but may appear on the nose and ears. The part affected becomes swollen, dusky, and there is pain and itching, sometimes leading to ulceration. Protection of the body, especially the hands and feet, from cold is the best and the only really effective way of preventing chilblains. Warm lined gloves and footwear, and warm stockings or trousers should be worn outdoors. Adequate heating of rooms is essential: a temperature between 18° and 21°C is recommended (65°–78°F). Most tablets, medicines, ointments, or creams for chilblains are useless. A skin affection caused by heat is rather grandiosely described as *erythema ab igne*, and is frequently seen on the legs of ladies addicted to roasting their legs before the fire. It takes the form of red patches on the front of the legs, and can be removed only by avoiding the cause.

Dermatitis means "inflammation of the skin," and therefore the word could be, strictly speaking, applied to any skin disease. In fact the term is used almost interchangeably with the term *eczema*. There are three main types of dermatitis or eczema. The first, *primary irritant dermatitis* results from injury of the skin by some powerful chemical, such as strong alkali or turpentine. The second, *contact dermatitis* is due to sensitisation of the skin to some substance which is normally liable to cause this type of allergic sensitivity; examples are nickel (in jewellery and suspender buckles), epoxy resins, rubber additives, primulas and chrysanthemums, and even ingredients of cosmetics. Contact dermatitis may continue for a long time, even after the patient is no longer in contact with the offending material. The third type is often called *constitutional eczema*. Although the skin is apt to react adversely to various irritants and sensitisers the major part is played by the personality, and there is often a history of eczema, hay fever or asthma in the family. Treatment is more difficult, but local corticosteroids and tar, sedatives and psychological treatment can be of great help. Infantile eczema also belongs in this category, but in most patients it disappears as the child grows up.

Impetigo is an infectious skin disease caused primarily by the streptococcus, but later often infected with staphylococci. It usually occurs on the face, and takes the form of blisters filled with pus on a red base; when the blisters burst their place is taken by yellow crusts. Impetigo is very infectious and easily spread by the fingers, dirty towels, or cloths; therefore, one of the first necessities is to prevent infection of others or reinfection of oneself by avoiding scratching and using a different towel each day, which must on no account be used by anyone else. Treatment is simple with an antibacterial ointment, so the main issue is prevention of contamination.

Sycosis or " Barber's Rash " occurs in men, and is similarly treated.

Urticaria or *Nettlerash* is a familiar skin disease in which itching weals appear on the skin, usually for no obvious reason. It is not infectious, and can be caused by nervous stress, certain drugs, allergy to some foods, or even exposure of the skin to cold. In some people it is possible to write on the skin with a fingernail: the " writing " appears in the form of weals. This is known as *dermographism*; it occurs in many normal persons as well as in many patients with urticaria. The antihistamine drugs are the most useful in the treatment of urticaria. Urticarial swelling of the tongue or throat must however be relieved at once and is treated by an injection of adrenaline.

Acne, or " *Blackheads*," is a condition found on the face and shoulders; its appearance is so familiar that no description is necessary. Acne is one of those conditions which is the end result of many factors. There is, first, a greasy skin, the result of glandular upset (which is why the disease usually occurs in adolescence); secondly, there is infection of the skin; and thirdly, there is blockage of the sebaceous ducts, which ordinarily allow the grease from the skin to pass out on to the surface. Since the condition starts with excess secretion of grease, ointments should never be used, and probably the best applications are drying lotions containing some sulphur preparation which inhibits secretion of grease. The face should be frequently washed, and it is possible now to obtain detergent solutions which are both antiseptic and prevent grease formation. In severe cases ultraviolet ray treatment may be necessary.

Rosacea. As has already been implied elsewhere, although the wages of sin may be extremely unpleasant, the wages of extreme virtue may be no less troublesome. Thus *rosacea*, in which the nose and cheeks become red and greasy and the skin coarsened, occurs alike in chronic alcoholics and elderly ladies with no vices other than a preference for strong tea. Both cases are associated with indigestion, since, regrettable as it may seem, strong tea and alcohol are about equally liable to cause the gastritis which may be at the root of this complaint. However, in many patients the chronic flushing is caused in other wa
and psychological factors are important.

Lichen Planus is one of the numerous sk
diseases which seem to be due to nervous states
tension. It may occur on any part of the bod
but is most common on the front of the forear
and legs. The rash takes the form of nodu
which are lilac in colour and have a dent on t
top; when these disappear a stain is left behi
There is severe itching. Treatment is a matter f
a doctor, as it also is in the case of *psoriasis*,
very common disease of largely unknown orig
which is extremely resistant to treatment.
tends to run in families. It takes the form
slightly raised papules, usually on the elbows a
knees; typically the papules are covered with d
silvery-looking scales. Apart from the rash, t
patient is usually in perfectly good health a
there is no itching. Many drugs have been us
in psoriasis, notably chrysarobin, and while it
not difficult to cause the rash (which may occ
anywhere on the body) to disappear in one ar
or even in all areas for a time it has a stro
tendency to return.

Warts, or *Verrucae* are familiar enough. Th
are caused by a virus, and are, theoretically
least, contagious (although having removed ma
warts, the writer has never found them co
tagious). Most frequently they are found on t
hands, but may occur elsewhere. Treatment
best carried out by a doctor, who will use
cautery, a caustic carbon dioxide frozen in
" snow ". A curious feature of the common wa
is that it can sometimes be caused to disappear
suggestion, which is presumably why so many o
wives charms are not necessarily without effe

and often causes a good deal of discomfort.
is best dealt with by a chiropodist or in bad cas
by a skin specialist since it is highly infectious.

Icthyosis is a disorder of horn formation wi
which some unfortunate people are born. T
oil and sweat-producing glands do not functi
well and the skin is dry and scaly like the skin
a fish. It is, however, possible to help the con
tion, which does not affect the general health,
frequent alkaline baths to wash off the scales, a
the subsequent use of lanolin to replace the lacki
oil. Large doses of vitamin A seem to help
some cases, and there have been reports in t
medical Press of cases being helped by hypnos
this, however, is very much a matter for specu
tion.

Cancer, Rodent Ulcer, and Cysts. Cancer of t
skin occurs mostly in old people, and takes t
form of what is described as an *epithelioma*. It
most common on the face or hands, and usua
appears as a nodule which breaks down a
produces an ulcer. The glands may later
affected, but such cancers can almost invariab
be cured unless a considerable time has elaps
during which they have been neglected. *Rode*
ulcer is a form of ulcer which appears on the inn
corner of the eye or the side of the nose in o
people. It does not spread over the body, b
acts by eating into the tissues in the area where
has started. X-ray or operation is necessa
but the outlook is good. *Cysts* on the skin a
due to blockage of the sebaceous glands. The
may become very large, and are best remove
as they may become infected. They do n
turn into cancer, and there is no such thi
as " male " and " female " cysts. It do
sometimes happen that *moles*, especially of t
bluish-black type, may become malignant, so
is perhaps best to have them removed surgica
when they exist. *All moles which change*
appearance or size should be at once referred to
doctor.

Skin Grafts.

These are a very complex subject which can
only briefly discussed here. They are us
basically for a number of conditions in whi
large areas of skin have been removed from t

, as in burns or serious accidents. In other
, as in plastic surgery, grafts may be used to
a new nose, eyelids, and so on. The follow-
re the main types:

nch Grafts are small, circular pieces of skin
from some other part of the body. (The
er method of using grafts from another person
been given up almost completely, since such
s—except in the case of identical twins—
" take.") The small pieces are laid on the
without skin and gradually grow together.
thickness grafts are grafts removed from
her part of the body by an instrument known
dermatome, which cuts sections about 4 in.
in. containing part of the deep layers of the

Full-thickness Grafts, on the other hand, the
thickness of the skin is removed from
here and applied to an area which has to
friction or heavy weights, such as the hand
e foot. Lastly, and this is largely used in
c surgery, there is the *Pedicle graft*, which,
tunately, although it is certainly the most
ng type, is rather difficult to describe.
y, if one, for example, wants to make a new

gs and physiotherapy.

Gout, so far as one knows, has nothing at all to do with rheumatism. It is a metabolic disease caused by the inability of the body to deal with certain protein breakdown substances, such as uric acid. Typically, the pain develops in the big toe, and the foods concerned are such luscious products as wines, spirits, liver, sweetbreads. Although drugs such as cinchophen can help, the plain fact is that those liable to gout cannot have sweetbreads and wine, liver and spirits, without having gout as well. Most people, perhaps, would prefer the food and wine, but those who dislike gout must abstain.

Fibrositis. All diseases are annoying to the patient, but fibrositis is just about equally annoying to the doctor. Fibrositis, in fact, is a condition in which people come along (and how often they do so!) with muscular pain which may be caused by anything from falling down the stairs to quarrelling with their mother-in-law. Although at one time, and perhaps even now, it used to be said that those with fibrositis could be diagnosed by the presence of " nodules " in their muscles, it is almost certain: (*a*) that there are no such nodules, and (*b*) that muscular pain may be due to many causes and very largely to psychological ones.

DISEASES OF THE EYE.

The Eye.

The eye is frequently compared to a camera, and in a general sort of way there is some resemblance. The eyeball consists of 3 coats within which are contained the refraction media: (1) The outermost layer, the main support of the eyeball, comprising the sclera (opaque) and the cornea (transparent, covering the front of the eyeball). The conjunctiva (the part which gets inflamed when you get germs or dust on the surface of the eye) is a thin protective membrane covering the sclera and doubles back to line the inside of the upper and lower lids. It stops at the junction of the sclera and cornea. (2) The middle layer containing many blood vessels which forms the choroid and, in front, the iris (the coloured part of the eye). The muscle in the iris enables its central aperture, the pupil, to contract in bright light, and to dilate in dim light. (3) The innermost layer of nervous tissue, the retina. The retina contains the expanded termination of the optic nerve which is part of the brain. Behind the iris is the lens, which is controlled by a series of muscles which increase or diminish its curvature, and thus produce, according to the nearness or distance of the object, a clear picture on the retina. Some of these parts may, of course, be affected by disease. Here we shall deal only with a few of the more common diseases.

Blepharitis is an infection of the eyelids which is easily recognisable from the red, sore appearance at the margins, the formation of crusts, and the falling-out of the eyelashes. If it has just developed, an attempt may be made to treat it at home with hot bathing and the so-called Golden Eye Ointment, but *blepharitis* is liable to become a chronic disease, and it is wiser to see a doctor. Penicillin cream or ointment can cure the disease, but must *never* be used save under medical advice; allergy to penicillin is commoner in the eyes than anywhere else, and in some cases patients have lost their sight through its use in this way.

Conjunctivitis is the result of infection of the conjunctiva, and the symptoms are the familiar ones of a feeling as if some grit had got into the eye, running from the eye, and frequently gummed-together eyelids in the morning. In some cases it can be treated by hot bathing and eye-baths with one of the proprietary lotions on the market, but it is much wiser to see your doctor, who can supply much more effective remedies and may save you a lot of unnecessary discomfort.

Other Eye Diseases. We can only mention briefly *keratis*, inflammation of the cornea;

iritis, inflammation of the iris; and *glaucoma*. These are all potentially serious diseases, and should not be diagnosed or treated by the layman. Glaucoma, in particular, may lead to blindness if help is not sought in time. If there is redness and congestion over the eye, dimness of vision, *severe* pain (as contrasted with the irritation caused by conjunctivitis), and perhaps even vomiting, the doctor must be called immediately.

The main disease of the lens is *cataract*, in which the lens becomes opaque and varying degrees of blindness result. Ordinarily, cararact is a condition found in people after middle age, but sometimes it is found in children at birth. The treatment is by operation—one which has been carried out for centuries—in which the opaque lens is removed. The patient thereafter has to wear glasses, but the vast majority of patients obtain good vision.

In *retinitis*, however, where the "screen" at the back of the eye is affected, the general outlook is more serious. This is because, whereas cataract is a localised disease, retinitis often signifies some bodily illness: infection, hardening of the arteries leading to hæmorrhage, diabetes, or kidney disorders. Sometimes the retina becomes detached, leading to blindness. As has been suggested above, except in very minor conditions such as styes (a localised infection treated in the same way as blepharitis), or conjunctivitis, the doctor should always be consulted. He should be consulted, too, when a foreign body gets into the eye unless it can be removed by very gentle manipulation with a handkerchief, for it must be remembered that such "poking about" on the surface of the eye may do much more harm than the original condition. So, if a couple of minutes fail to remove the grit, give up, and go to the surgery.

DISEASES OF WOMEN.

The *internal sexual organs* of a woman, like the urinary system, can best be described as shaped like a capital Y. At the tips of the arms of the Y are the female sex glands, the ovaries: the two arms running downwards are the Fallopian tubes: the point where the arms meet is the womb or uterus: the single leg of the Y is the vagina. These are the *primary sexual organs* of a woman and they undergo regular cyclical changes in response to the control exercised over them by the pituitary gland, situated in the base of the skull. This control is mediated by chemical messengers (hormones) secreted into the circulation. The ovaries also secrete hormones, œstrogen, and progesterone, and a delicate hormonal balance is maintained between the pituitary gland and the ovaries. Each month an egg cell (ovum) matures and is released from the ovary, usually midway between two menstrual periods: the ovum is wafted along the Fallopian tubes by waves of contraction and if fertilised embeds in the lining of the uterus which has been conditioned to nourish it by the ovarian hormones. If it is not fertilised the ovum escapes from the uterus, altered hormone levels then cause the lining of the uterus to be shed (this is menstruation), usually about 14 days after ovulation. After menstruation a new cycle begins: another ovum matures and a fresh lining grows in the uterus. These cyclical changes recur from puberty to the menopause. Menstruation does not occur during pregnancy, of which a missed period is often the first sign. However, women do miss periods even though they are not pregnant, and this usually means that some minor and temporary change has occurred in the hormone balance. If three consecutive periods are missed it is wise to consult a doctor.

The *breasts* are called *secondary sexual organs* and are also under the influence of the ovarian hormones. Women are sometimes worried because they believe that their breasts are either too small or too large. However, small breasts cannot be made larger and are just as efficient for feeding babies as large ones, which are not always as effective as they appear. If breasts become too large they can be dealt with by plastic surger Two conditions which do need treatment a *mastitis* and *cancer of the breast*, both of which a characterised by lumps within the breast tissu Mastitis may be uncomfortable but is n dangerous and can be treated medically, wherea cancer is more serious. The distinction betwee mastitis and cancer can only be made by a doct and any woman who discovers a lump in h breast must seek medical aid *at once*.

Abscesses also occur in the breast, nearly alwa when the mother is feeding her child. He again, a lump appears, the breast becomes r and very tender, and the woman may be feveris Treatment with antibiotics is sometimes succes ful, especially if the mother consults her doct quickly, otherwise treatment is by a small oper tion.

The Ovaries. The two commonest diseases the ovaries are cysts and disorders arising fro hormonal imbalance. The symptoms of ovaria disease are usually abdominal or low bac pains, and heavy and painful loss during th periods, which may become irregular. Thes signs should be taken as a warning to consult doctor.

The Fallopian Tubes. Infection of the Fa lopian tubes is called salpingitis. The membran lining the tubes is continuous with the lining the uterus, hence an infection is rarely confine to a circumscribed area in either the tubes or th uterus, and pelvic inflammatory disease is a bette name for this condition. Pelvic inflammator disease often follows an abortion, or childbirt where part of the afterbirth (placenta) has bee retained, or can spread from an infection in nearby organ, for example the appendix. Infection is sometimes conveyed by the blood fro another septic source in the body. The gon coccus is another cause of infection. The diseas is characterised by pain and tenderness in th lower part of the abdomen, accompanied by feve general malaise and frequently (but not invariabl a vaginal discharge. The treatment of pelv inflammatory disease is usually medical and the same irrespective of the primary site infection. Before the introduction of antibioti the disease often became chronic and the Fallopia tubes were frequently blocked by a cicatrisin scar, a cause of subsequent sterility.

The Uterus. This is a hollow muscular orga and both its musculature and its lining membran can be the site of disease. *Fibroids* are non malignant muscular tumours which develop many women. The main symptom is a heav menstrual loss and surgical removal of the uteru (hysterectomy) is often necessary. This is major operation, but modern anæsthesia an operative techniques minimise the discomfor Hysterectomy does not impair sexual pleasur but no more babies can be conceived. Infectio of the lining of the uterus is usually part of generalised pelvic inflammatory disease (se Fallopian tubes).

Cancer of the Uterus and Cervical Smears. Th uterus is pear-shaped and consists of a body an neck. The wide end is uppermost (the body) an the narrow neck (cervix) projects into the to of the vagina. Cancer of the cervix is commones in middle-aged women who have married youn and have had a large family; cancer of the bod of the uterus usually occurs after the menopaus and is most common in childless women. Th symptoms are variable and it is sufficient t emphasise that any woman who has unexpecte bleeding, especially after intercourse, whethe her periods have stopped or not, *must* see he doctor at once. The treatment depends o individual circumstances, but is usually b operation. It is now possible to detect canc of the cervix long before symptoms develop an at a stage when the disease can be eradicated by relatively small operation. This early detectio has been made possible by the development exfoliative cytology. Cells taken from the cervi (without discomfort to the woman) are examine

r a microscope. This test is popularly known
he "cancer test" or "cervical smear." A
cal smear is often taken as part of the routine
ecological examination by consultants, general
titioners, and family planning doctors, and is
being included in some population screening
rammes. It is a big step forward in pre-
ive medicine and may ultimately solve the
lem of cancer of the cervix. Every woman
een the ages of 25 and 60 should seize any
ce to have this test done.

olapse means a sagging down of the uterus
the vagina and the cervix may even appear
e outside. It is a result of frequent childbirth
laxness of the ligaments which support the
s: weakness of the vaginal walls often occurs
e same time. The symptoms of uterine
pse are low back pain and a heavy dragging
g in the lower abdomen: these are often
hadowed by the distressingly embarrassing
tinence which results from lax vaginal walls.
stress of only a sneeze, a cough, or a giggle
causes the involuntary escape of urine. The
is operative and very rewarding.

scharge (*Leucorrhœa*). A white discharge is
l leucorrhœa. It is normal for a woman to
a white odourless discharge: medical help
d be sought if a discharge becomes offensive,
duly watery, is bloodstained or causes irri-
n. A discharge can originate in the Fallopian
and uterus, for example in pelvic inflam-
ry disease, but is more commonly due to an
tion of the vagina by bacteria or fungi. A
al discharge causes the patient a great deal
comfort and misery but as soon as the exact
has been found treatment is speedily
ved by cure.

e change of life or *Menopause* is the outward
festation of a change in the hormonal balance
woman's body: the periods stop and she
o longer conceive. Many women are very
led at the prospect of the menopause, and
s not unnatural for nobody likes growing
This natural apprehension is overlaid
all sorts of irrational fears largely based on
wives' tales." Heavy losses of blood,
h of facial hair, depression, loss of sexual
ure, and frequent hot flushes are not an
able burden. The commonest symptoms
t flushes and depression, but both are usually
ly relieved by small doses of hormones,
ially if the woman consults her doctor when
ymptoms first appear. At the menopause
ds may stop rapidly or become irregular
inally cease: sometimes a woman misses
more periods, then periods re-start and this
may be repeated several times before men-
tion finally stops. The pattern at the
pause is as varied as woman herself—but
oman has had no period for two years and
notices spotting or bleeding she should
lt her doctor to make sure that all is well.
menopause has no influence whatever on
l life (although naturally it has on fertility)
esire is not affected. It is recounted that
ous courtesan, at the age of 80, on being
by Voltaire when women ceased to feel
, replied, "I don't know—I haven't lived
nough."

menorrhœa or pain with the periods, is very
on and most women experience this
om at some time or another. Very often
s first periods are troublefree, but dysmenor-
develops after a year or two: this suggests
psychological element is involved. Dys-
rhœa is a symptom which has many varying
, and the sensible thing to do, if pain is
esome, is to see a doctor.

enorrhœa means stopping of the periods in
ng woman. It may signify pregnancy or
lar disease or it can be purely psychological.

rtion is a word which does not necessarily
any criminal act, for abortion, or its more
able name, miscarriage, describes the spontaneous or induced termination of a pregnancy before the fœtus (baby) is able to survive. A baby cannot live unless it is born after the twenty-eighth week of pregnancy, though many infants born at this time die. The two main symptoms of abortion are bleeding and abdominal pain. Any bleeding occurring during pregnancy ought to be reported at once. Pain starts in the back and lower abdomen and is usually spasmodic in character, and like colic it works up to a peak and then temporarily passes off. Any pregnant woman with pain and bleeding should go to bed at once and send for her doctor. *Criminal abortion* is brought about deliberately either by the use of drugs or by injecting substances into the womb. Both these practices are extremely dangerous: there are no drugs which can produce an abortion without also endangering life, and an injection into the womb is likely to cause a serious infection (pelvic inflammatory disease) and sometimes death. The immediate risk to life and the not inconsiderable risk of sterility and chronic ill-health is too often the price of a criminal abortion: the price is too high and should never be paid. When doctors are convinced that a pregnancy may endanger the health of the mother then an abortion by safe surgical means may legally be performed in hospital.

CONTRACEPTION.

If a couple intends to practice birth control expert advice should be obtained from their family doctor or family planning clinic. The matter of whether or not a baby is born is too important to leave to chance. The method chosen must be effective as well as acceptable to the couple concerned, and the extent of the choice only emphasises the fact that the ideal contraceptive which is best for every couple at all times has yet to be discovered. The only method which is 100 per cent. reliable is abstinence. If the male seed (sperm) fertilises the female seed (ovum) then pregnancy results. Contraception is only effective if this union is prevented. A couple can achieve a measure of contraception without the help of pills or appliances if the husband practices *coitus interruptus* or they rely on the wife's "safe period." *Coitus interruptus* (when the man withdraws before emission occurs) is a thoroughly unreliable method which often leads to psychological difficulties in both partners. The "rhythm" or "safe period" method relies on estimating the time of ovulation and abstaining from intercourse during this time. This is at best unreliable, though its effectiveness can be improved by keeping careful records of the body temperature on waking each morning as the temperature rises once ovulation has occurred. The interpretation of these temperature records needs care and couples who must rely on this method can obtain expert advice from, for example, The Catholic Marriage Advisory Council, or a family planning clinic. *Barrier methods* prevent the sperms from reaching the ovum and can be used by the man (sheath or condom) or woman (cap or diaphragm): the reliability of the barrier is greatly increased if it is used in conjunction with a spermicidal cream, jelly, or pessary. A great many women have found that the *oral contraceptive pill* is ideal for their needs: it is the mose æsthetic means of contraception and offers the most complete protection against pregnancy. Oral contraceptive pills contain chemical substances (œstrogen and progestagen) which replace the hormones normally released from the ovary while an ovum is developing. Ovulation does not occur, and without an ovum there can be no pregnancy. Pills must be taken strictly as directed as the dose is the lowest that will provide effective contraception and missing a tablet may result in pregnancy. Side effects sometimes occur (for example, nausea, breast discomfort, headaches,) but usually decrease after a few cycles of medication. Newspaper reports of the deaths of young women taking the pill have caused widespread concern. These tragedies have followed blockage of a blood vessel (by thrombosis or embolism) and have been carefully investigated, and the conclusions are that the number of such deaths is small and does not

differ from the number which would probably have occurred in any case. No satisfactory pill for a man has yet been developed. In the newest method of contraception a small plastic *intra-uterine device* (loop, bow, or coil) is inserted into the womb. Once inserted it can be forgotten: a tremendous advantage to many different peoples and societies. It is not as effective as the pill
but is more satisfactory than barrier method
This intra-uterine device is not suitable for a
women and is usually not recommended to wome
who have borne no children or who have ver
heavy periods. However, careful selection
suitable women has resulted in a high proportio
of satisfied users. The search for the idea
contraceptive continues.

PART III. SPECIAL TOPICS

UNDERNUTRITION AND THE DEVELOPING BRAIN

The following article is about some relatively new ideas about the effects of quite minor undernutrition on the growing brain. The author wishes to emphasise that, at the present stage, they are scarcely more than *ideas.* It is reasonable to put forward speculative hypotheses of this kind only if they can be tested by experiment, and provided no one is misled by them before this has been done. The reader is hereby warned!

Considering the enormous amount of research which has been carried out into the effects of undernutrition on the various tissues of the body, it is surprising that its effects on the brain have been so neglected. For those (the majority) who survive a period of infantile undernutrition, damage to the brain is presumably of more concern than any other effect, and yet we know so little about it. This may be due to a long-standing belief among nutritionists in the "sparing" of the brain by undernutrition, based on the common finding that even when the other tissues, like muscle, are wasting away, the weight of the brain is unaffected. Research workers have probably not seen much future in examining a tissue so resistant to restriction, even though in early life the developing brain is far from completely spared.

Early Undernutrition: its later sequelae.

It is now being suggested that the brain may not only be affected by infantile undernutrition at the time, but that the effects may even be permanent, provided they occur early enough in life. It seems that if the brain is to be permanently affected, the restrictions on it must be imposed at a time when it is undergoing its period of fastest growth. In most species this is before the growth spurt of the other organs, and in humans it corresponds to the last weeks of normal gestation, and, to a lesser extent, the first weeks of life.

A series of scattered observations—no more than straws in the wind at present—have led to this hypothesis. From various parts of the world, as far apart as South Africa, Mexico, and Yugoslavia, doctors have taken the trouble to keep records of babies who came under their care with severe protein-calorie undernutrition, and to follow their progress as children, long after apparently successful treatment of their condition. Their later intellectual capacity as older children has been shown, like their stature, to be smaller than in control groups of children drawn from the same communities who did not suffer such severe undernutrition as babies. By contrast, it has been claimed that deprivation later than the first few months of life produces similar delays in neurological development at the time, but that these are recoverable with return to normal nutrition, the stress having occurred too late in the course of brain development to produce permanent effects.

Low Birth Weight, Small Stature, and Intelligence.

It is already known, mainly from studies in experimental animals, that there can be permanent effects on body size following very early deprivation of food, which do not disappear however much food is subsequently supplied. It is also known that stature in humans is in some way related to intellectual capacity, and it is just possible therefore, that there are some physically
small, not-very-bright people about in the worl
whose mental and physical deficits may both b
traceable to restrictions at the time their brain
were growing fastest. Of course it is extremel
important to understand that the correlation
small stature with small intellectual capacity
only true in the statistical sense, taking larg
groups of people and removing their "individu
ality" by expressing them as averages. We a
know lots of small people who are highly intell
gent; and there are plenty of big ones without a
idea in their heads. Nevertheless, statistically
has been found to be true of such diverse groups a
London eleven-year-olds, French conscripts, an
Aberdeen ladies pregnant for the first time (wh
happen to have been examined from this point
view!) that size goes with intellectual performanc

It may also be significant that people who wer
born prematurely, or of "low-birth-weight-fo
dates", have an intelligence on the average
little less than those born normally at full term
Here, again, there are plenty of famous peop
who were small at birth, and the correlation is onl
a statistical one. Nevertheless, they might hav
been expected to be generally of smaller statu
and have somewhat smaller brains if the idea out
lined above has any validity.

It must be admitted at once that any dire
connection between early deprivation during th
period of brain development and intellectu
deficits in later life is pure speculation. The
must be many other perfectly good reasons for th
connections which have been found between th
two. For example the more seriously underfe
babies in any community are likely to belong
the less intelligent parents from the least privilege
socio-economic categories: and inherited facto
must play a large part in subsequent performanc
The less intelligent parents will generally provid
a poorer physical and intellectual environment fo
their children, even after their gross undernutritio
has been treated. Nevertheless, in the observa
tions mentioned above, some care was taken
match the underfed babies with control groups
the same ethnic background, under similar soci
economic and geographical conditions. And r
turning to the presumably less severe example
low-birth-weight babies in our own more privilege
communities, there is a statistically demonstrab
difference even between twins. The twin
smaller birth weight than the other tends to fa
worse in bodily stature and in intellectual pe
formance later. In this case many of the troubl
some variable factors, both genetic and enviro
mental, must have been common to both twins.

A Hypothesis.

The most that is being claimed at this stage
that the following hypothesis seems a sensible o
and is worth testing. Let us see if there is a vu
nerable period during the physical development
the brain, corresponding to its period of faste
growth, when unlike the adult brain, it is su
ceptible to deprivation. Furthermore, sin
brain development is in many ways a once-and-fo
all process, is it possible that damage inflicted
this time will be permanent? Finally, we sha
need to demonstrate a connection between th
physical development of the brain and its intelle
tual capacity before the idea can have mu
practical importance.

It must immediately be confessed that we are
long way at present from a properly conduct
investigation of this hypothesis, but it is bei

orted increasingly by the results of animal riments, and there is considerable theoretical ort from our knowledge of the growth and lopment of the normal brain. It is clearly ssible to test the idea experimentally in ans; and although observation and follow- in underdeveloped human populations is ntly being attempted along these lines, the tical and technological problems involved are h more difficult than they at first appear, and ollow-up period is inevitably long. For this n we are virtually restricted at present to al experiments, with all the attendant ulties when it comes to interpreting the results man terms.

n Growth and Myelination.

uch of the growth of the brain at the time of astest growth is concerned with myelination erve fibres, since the adult number of nerve is already almost complete. Myelin sheaths nanufactured by oligodendroglial cells which ude a double spiral of their own cell mem- es, wrapping it around the nerve axons like ghtly packed, fatty Swiss roll. Myelin is simply because cell membranes are fatty, very many layers make up the myelin sheaths, h in turn make up so much of the bulk of the brain. The process of myelination consists y of a dramatic increase in the number of dendroglial cells, followed by mass production hese cells of the various fats destined to be in- rated into myelin. It has long been sus- d, but has only recently been directly nstrated, that once many of the materials uilt into the sheaths, there they will per- ntly remain, probably throughout life. myelination has occurred the brain loses its city to make myelin, and in the adult brain iochemical mechanisms which were so active g development have largely disappeared. may incidentally be a reason why myelin in dult central nervous system cannot regene- vhen damaged, or when lost in demyelinating se.

elination is therefore one of the once-and- l processes in the developing brain. There wo theoretical dangers in such a process. is that the wrong kind of material may be ocably laid down—and there is a suspicion this may be one of the factors responsible for elinating disease (multiple sclerosis) in later The other danger, with which we are at nt concerned, is that if the opportunity to sufficient myelin (or to produce sufficient o make it with) is lost due to adverse condi- at the time of its development, the oppor- y may be lost for ever and a *permanently* n-deficient brain produced. Our hypothesis this period in brain development may be a ularly vulnerable one has, therefore, ent theoretical support to make it worth g in the experimental animal.

iments on Animals.

e of the main questions to decide in using mental animals, is whether the results are to have any meaning for our own species; far as myelination is concerned the answer ssuring. In all mammals, and indeed in other forms of life, the manner of myelina- from oligodendroglial cells) and the nature biosynthetic processes are identical. Also mposition of the myelin once formed is so r from species to species, that there are no s difficulties there. However, there is one ntial species difference which must be d for, and that is in the timing of the pro- n relation to birth. In man myelination is eight in the few weeks before birth. In the pig, however, with a gestation period of 65 he peak rate of development is at about 45 f *fœtal* age. The extraordinary maturity guinea pig's neurological performance at must have been seen by anyone who has o catch one within an hour of its emergence e world. By contrast, the rat is very immature at birth and only achieves its brain "growth spurt" during the second postnatal week. It can be seen that if our hypothesis has any validity at all, guinea pig brain should be more vulnerable *before*, and rat brain *after* birth. In the case of man, vulnerability will be at its height in the last few weeks of normal gestation, and the first few weeks of postnatal life. This is the very time when prematurely born babies must suffer a rather brutal separation from their maternal dependence; and when "low-birth-weight-for-dates" babies are presumably suffering most from whatever placental insufficiency may be responsible for their condition.

Mild Undernutrition in Suckling Rats.

Since it is clearly impossible to perform undernutrition experiments on human babies, scientists have resorted to the use of rats, which are particularly convenient for the purpose, since their entire, postulated "vulnerable period" is postnatal. They are therefore accessible and their food intake can be regulated at various times in relation to this period. Normally rats suckle for the first three weeks of their lives, by which time they are beginning to nibble solid food pellets and can be weaned. Their fastest brain growth occurs entirely within the suckling period. Now, it has been known for some years that quite minor variations in their intake of milk at this particular time can produce permanent changes in their ultimate body size.

Rats are normally born eight to ten in a litter. If two litters, born on the same day, are mixed up in a basin, and three of them awarded at random to one mother and the remaining fifteen or so to the other, the mothers will rear them quite satisfactorily. But at the time of weaning, the privileged rats from the smaller litter will weigh much more, and be much more mature than the underprivileged ones from the larger litter. The interesting thing is that even if they are all weaned on to an *ad libitum* diet, and given as much food as they wish to eat for the rest of their lives, the smaller rats never catch up with the larger. If, however, the rats are reared normally for the first three weeks, and are *then* undernourished, even quite severely and for longer, complete "catch-up" can be achieved when they are restored to a normal diet.

The Brains of Rats Undernourished at Different Ages.

The brains of such animals have been examined at various stages, as have the brains of severely undernourished *adult* rats. The total numbers of cells in the brains have been "counted" by a chemical estimation of the deoxyribose nucleic acid (DNA) in them. There is the same amount of DNA in every nucleus, and this is a much easier way of "counting" cells than with a microscope. An idea of the amount of myelin present has been estimated from a chemical estimation of brain cholesterol, since this is a characteristic myelin lipid. The rate curves of normal accumulation of these "markers" correspond well with what we know of the normal myelination process: that lipid deposition is preceded by glial cell multiplication.

The results show that although very early undernutrition spares the brain more than the body, there are still quite serious deficits in the brain even though the undernutrition was mild. Also, recovery of the brain was not complete by the time of maturity. By contrast, much more severe undernutrition applied only a little later (and for longer) produced no demonstrable effects on myelination although the brains were smaller than they should have been. However, in *this* period recovery was complete in all measured respects. Part three of the experiment showed that the maximum severity of undernutrition which is possible in *adults* had no effect whatever, even on the weight of the brain. Furthermore, none of the brain constituents measured were at all affected. Experiments are still in progress to determine the extent of rehabilitation possible in the mildly- (but early-) underfed rats, but it is already known from experiments using growing pigs that it is possible to prevent complete recovery in terms of myelin fats as well as in numbers of glial cells.

Of course in human populations living in underprivileged conditions throughout the world, undernutrition rarely occurs in short bursts, to be followed by restoration of an abundant diet. In an attempt to design animal experiments with a greater resemblance to the human condition it will be necessary to investigate the effects in rats of early undernutrition followed by continuing shortages after weaning, and experiments along these lines are already in hand.

The Link with Subsequent Behaviour.

Even though we admit that we still lack a complete demonstration of our hypothesis that the physical development of the brain can be permanently retarded at an early stage, it seems clear already that the idea was a good one. Nevertheless, the final link in the chain of cause and effect is probably going to be the most difficult to demonstrate: that is the relationship of the physical composition of the brain to neurological and intellectual performance. It is entirely possible that the things we are measuring may have little to do with things that matter to the functions of the organ. All that is claimed at present is that the evidence from the behavioural testing of rats together with the necessarily scrappy evidence from human sources mentioned earlier, is sufficiently alarming to make this an urgent matter for investigation.

Conclusions.

Psychologists have long believed that the learning of certain skills during development can be a once-and-for-all process, which, if missed at the time is missed for ever. We may now have a physical counterpart to this same idea. There are known to be vulnerable periods at the very beginning of brain development (in the first few weeks after conception) when viruses, drugs, and abnormal vitamin supplies are known to affect the *shape* of the brain, resulting in gross morphological anomalies. From the evidence presented here it may be that, towards the end of (human) pregnancy and soon after birth there is another vulnerable period in which quite minor restrictions can affect the *rate and ultimate extent* of growth of the brain rather than its *shape*. If so, this will have significance not only for the severely undernourished babies in underprivileged communities, but equally for babies of low birth weight in populations whose general nutrition is good.

THE PHYSICAL BASIS OF MEMORY.

It is said that once you learn to swim you can't forget it. Why is this so? Is there something in the brain which stores these experiences and manifests itself when required? We often forget names of people recently introduced to us or the name of a new place, and certainly recently known very important telephone numbers, whereas we remember in minute detail anything we have learnt gradually or over a long period.

Memory Research.

For about a hundred years, scientists have tried to establish the process by which an organism stores its experience and uses it later. In the early 1920s the discovery of Berger that the brain undergoes continuous electrical activity led to an "electrical" theory of memory, in which a certain experience reaching the brain sets up within it a unique pattern of electric currents involving many nerve cells. The simplest circuit would require 3 nerve cells and each of these could form a part of a large number of circuits. Hence the number of combinations available in a brain containing about ten thousand million nerve cells (
does the human brain) is quite impressive and
sufficient for storing enough memories to last
lifetime. Each experience would be represente
by a particular circuit of nerve cells around whic
circuit electric current continuously reverberate

In 1940 Karl Lashley used ablation techniqu
to try to localise a particular area for memory
the brain. In fact what he did was to remov
certain areas of brain in animals and note th
effect on memory, or on learning of a particula
skill. Although he did not find such a localise
area, he was at least successful in resolving tw
important features in the memory controvers
He removed quite large areas of brain and cu
several fibre connections, thus abolishing an
preformed circuits, without noting any detr
mental effect on learning behaviour. This e
ploded the hypothesis of reverberating circuit
Another conclusion was that the process of lear
ing lies somewhere in the cells themselves, as th
impairment of learning in the animals was pr
portional to the size of the area removed fro
the cortex. So clearly some permanent chan
must occur within the cell itself when memo
is established. But such a permanent chan
must demand a chemical as well as a structur
change or modification in a specific set of ner
cells, as any change in a cell would require th
production of new biochemical substances.

So started the hunt for chemical substanc
whose amounts change during learning in such
way as to relate to the learning activity. An
such substances must be in the cells themselve
and must be extremely stable after they a
formed so as to withstand severe alteration
environmental conditions because of the immen
stability of memories once formed.

The Key Substances.

Of the many substances, three components
cells fulfil the above criteria. They are the n
cleic acids DNA and RNA and proteins. B
about 1950 molecular biologists had establishe
that DNA acts as the carrier of the genetic co
which is passed on from parents to the offsprin
DNA serves as a template for synthesis of RN
which in turn serves as a template for prote
synthesis. As learned behaviour is not inherite
but formed due to the demands of the enviro
ment, it is reasonable to suppose that either RN
or proteins or both are the key substances we a
looking for which change during learning. O
hypothesis, for instance, was put forward in 19
that nerve cells store memory traces by means
the production of a particular kind of RN
molecule, and that this in turn influences t
ability of a nerve cell to form connections wi
those adjacent to it, hence enabling new circu
to be formed.

If RNA is responsible for learning, and if
could inhibit RNA synthesis, then we should al
impair learning. Fortunately, there is a su
stance (known as 8-aza-guanine) which does pr
vent the production of RNA. It was found th
if a group of animals were injected with this su
stance, they would take more time to learn the
way through a maze and make a greater numb
of errors than control animals. But 8-aza-guani
cannot abolish the memory or the way throu
the maze once it has been learned and establishe
This implies that memory once formed cannot
abolished by depressants of RNA synthes
Similarly Flexner and his co-workers, amo
others, have found that drugs which hamper pr
tein synthesis also hamper learning.

Short-term and Long-term Memory.

It has been found that electric shock, if appli
within 30 to 60 seconds after learning, could wi
out the memory, whereas it is quite ineffective
applied after 60 minutes or more. This indicat
that memory fixation occurs in two stages, t
first of short-term, the second long-term. Ame
can researches report that short-term memo
can be abolished by depressants of protein sy

is such the antibiotic puromycin, whereas
as much harder to abolish long-term memory,
old memory. McConnell, Kimble, and Jacob-
worked with flat-worms which are taught to
ond to a flashing light by contraction. These
ns also have the useful property of being able
egenerate when cut in half. The American
kers cut the trained worms into two halves,
half being capable of generating a complete
al. They found that the two daughter
ns thus produced responded to light flash as
he parent worm, which implied that the learn-
of the parent was present in both halves of
body and the learning was not erased even
this drastic treatment.

her workers claimed that if the flat-worms
kept in pond-water containing traces of
nuclease (an enzyme which breaks down
), the worm regenerated from the old head
could remember whereas that from the old
part could not, which pointed to the assump-
that (i) RNA is responsible for memory in
sfer of traces; (ii) RNAase blocks memory
sfer from the old tail to the new head;
it could not erase the memory trace already
olished in the old head.

ory Transfer Experiments.

ow comes the big question. Is learning trans-
le? The flat-worm experiments suggested
we were on the verge of a major breakthrough
e study of memory, learning, and animal
viour. McConnell, Jacobson, and Humph-
n America reported that if a trained group of
ns were chopped up and fed to untrained ones,
acquired the training of the unfortunate
ed ones. (However, English worms, true to
ld British tradition, apparently being more
sticated and civilised than their transatlantic
terparts, refused to exhibit such cannibalistic
es.) This apparent transfer could be due
r to a specific coded RNA or to the non-
fic addition of more RNA to an animal.

e next experiment was to extract the RNA
a group of trained worms and also from a
al group of untrained worms and inject it
two groups of untrained worms. The result
quite dramatic. The group which received
from the trained animals exhibited a very
ed improvement and learned more quickly,
ared with the control group which received
from untrained ones. Can this experiment
tended to more complex organisms such as
mals? Several workers have reported that
ined rats injected with RNA from the brains
ained rats apparently receive the training
gh RNA. Others have claimed that this
fer of memory trace could also work between
ent species, *e.g.*, by injecting RNA from the
s of trained hamsters into untrained rats,
claimed to be able to transfer learning to
at from the hamster. However, several
research groups have failed to reproduce the
iment.

and Memory.

hough the flat-worm can be conditioned to
nd to a certain stimulus and this response
be transferred, this could hardly be called
ry as we know it, or experience it. Holger
n of Göteborg has worked for about two de-
on the development of a micromanipulative
ique which enables him to isolate individual
cells and study their metabolism in isola-
He uses an ultra-thin steel wire loop
ted on a glass rod and fishes out large
ns from the rabbit brain. He and his co-
rs found that the RNA content of nerve
s much higher than that of the surrounding
Also the composition of RNA of the nerve
s apparently rather special. RNA is made
four bases: adenine, guanine, cytosine, and
in varying proportions. The relationship
en the bases and the order in which they are
ed on the molecule is unique for each type
A molecule (**F, Part II**). Hyden found that
nount of adenine and uracil in nerve cells
ne same as in the surrounding (glial) cells
as nerve cells contain more guanine and less
cytosine. He stimulated the sense of balance of rabbits by rotating them in a cage for 25 minutes a day for up to 7 days and dissected out the nerve cells responsible for control of balance. He found quite important changes in the base composition of RNA in other experiments where he trained animals to balance on a steel wire. All of these types of experiment point to the proposition that RNA is directly involved in learning or the establishment of the memory trace.

Protein Synthesis and Memory.

Similarly, there is evidence that changes in protein synthesis occur when stimulation of the brain takes place. Thus if an animal is subjected to a certain stimulus there is increased protein synthesis in the area of the brain which is responsible for analysing that stimulus. Very recently, experiments have also suggested that at the same time as the increased protein synthesis occurs, certain structural changes in the cell, observable in the electron microscope, also occur. Such structural changes could relate to the making of new connections between one cell and its neighbour.

Memory and Old Age.

It is not uncommon for old people to forget recent events but to remember in salient detail past experiences. Also old people tend to misplace the date, name or place of a particular past event even though it left a profound impression on them. Generally, memory, and certainly the aptitude for new learning, seem to decline with the advent of senility.

It is reasonable to assume that this decline in memory is in some way related to the general decline in the biological and biochemical activity of the brain in old age. It may be that the substances which are responsible for memory storage, which help an individual to learn and code an experience for future use, are not being produced in sufficient quantities, or even that the already established memory traces are being destroyed with the general decline of biological activity. Treatment with certain hormones in bringing about a general improvement in metabolic activity seems to be beneficial in helping such people to recover memory. Several research groups are investigating this problem.

Conclusions.

Thus, to summarise the biological evidence, we find that, during the establishment of the memory trace, there is increased brain activity, increased protein synthesis and active modification of increased numbers of previously non-functioning units. We know that RNAase impairs memory establishment, as do depressants of protein synthesis. It is now reasonable to put forward the hypothesis that the substances involved may not be pure RNA, nor pure protein, but may instead be a complex of RNA and a small protein. This would account for the process being destroyed both by RNAase and by inhibitors of protein synthesis.

As new facts are coming to light almost every day, it is hoped that the problem of the theory of memory can be solved within the coming years albeit drastic modification of our present concepts and ideas will almost certainly be necessary. Some of the more romantic possibilities opened up if the transfer experiments were found to be true could signify that the day may not be far off when we could transfer a particular skill from one man to another. Thus we could revolutionise the whole retraining programme in industry if we had sufficient RNA, protein, or whatever it may be, in stock to inject into a new group of recipients. We could even synthesise substances in the laboratory which represent a certain special skill and inject them to unskilled workers transforming them into skilled workers overnight. All this is certainly sensational wishful thinking and surmise. But there is no reason (in all seriousness) to doubt that memory storage has a biochemical basis, and that the problems of memory and memory transfer can be solved in our lifetime.

PART IV. INDEX AND GLOSSARY

Abdomen. The part of the body below the chest and above the thighs.
Abortion. The termination of pregnancy, from whatever cause, before the child is capable of independent existence, 57 (1).
Abortus fever. An infectious disease known as undulant fever, 15 (1).
Abrasion. Any injury which rubs off the surface skin.
Abscess. A collection of pus enclosed anywhere in the body.
Acidity. *See under* **Peptic ulcer,** 35 (1).
Acne, 54 (1).
Acromegaly. A state of excessive growth of the body caused by overaction of the pituitary gland in the base of the brain, 44 (2).
ACTH. An abbreviation for adreno-cortico-trophic-hormone, a drug related to cortisone.
Actinomycosis, 15 (2).
Acute nephritis, 45 (2).
Addiction to drugs. *See* **Drug abuse,** 22.
Addison's disease, 44 (2).
Adenoids, 32 (1).
Adhesions. An occasional cause of pain after operations when abraded areas adhere to each other.
Adreno-genital syndrome, 44 (2).
Air we breathe, 4 (1).
Agranulocytosis, 26(1).
Alcoholics Anonymous, 6 (2).
Allergic rhinitis, 31 (2).
Allergy. Abnormal sensitivity to any substance which does not affect normal people, 34 (1).
Alopecia, 53 (1).
Amenorrhœa, 57 (1).
Amnesia. Loss of memory, *see under* **Neurosis,** 51 (2).
Amœbæ, 8 (1).
Amœbic dysentery, 17 (2).
Amphetamine, 23 (2).
Amyotrophic lateral sclerosis, 49 (2).
Anæmias, 24–25.
Anæsthetic. Any drug used by surgeons to remove pain during an operation.
Aneurism, 30 (2), 47 (1).
Angina pectoris, 28 (2).
Angio-neurotic œdema, 49 (2).
Ankylosis. Partial or complete fixation of a joint as after some types of arthritis. In other cases deliberately produced by surgery.
Ankylostomiasis, 16 (2).
Anorexia. Loss of appetite.
Anthrax, 15 (1), 9 (1), 4 (2).
Antibiotics, 9, 4, 22 (2).
Antihistamine drugs, 4 (2), 5 (1).
Antiseptics, 8 (2).
Antitoxins. *See under* **How the Body Deals with Infection,** 8 (2).
Anxiety neurosis, 51 (2).
Aortic diseases, 30 (2).
Aphasia, 48 (1).
Aplastic anæmia, 25 (1).
Appendicitis, 37 (2).
Arteriography, 47 (2).
Arthritis, 55 (1).
Artificial respiration (kiss of life), 21 (1).
Ascites, 39 (2).
Asphyxia, 20 (2).
Aspirin and "upset stomach", 5 (1), 23 (1).
Asthma, 33 (2).
Atheroma or Atherosclerosis, 30 (1).
Athlete's foot, 8 (1), 15 (2).
Auscultation. The method used by a doctor when he listens for signs of disease inside the body by means of a stethoscope.
Autonomic Nervous System, 47 (1).
Backache. A symptom which may be caused b many different diseases—sometimes disease the vertebræ themselves, sometimes strain the ligaments, and sometimes inflammation spasm of the surrounding muscles. "Lumbago" is usually due to inflammation of th muscles in the small of the back. Backach from purely local causes may be treated temporarily by applying heat in the form of kaolin poultice or a rubber hot-water bottle an taking two aspirin tablets a day. On the othe hand, many cases of backache are due to diseas elsewhere. The most important thing is to fin out the cause, and therefore a doctor should b consulted. *See also* **Fibrositis** 55 (2).
Bacteria, 7 (1). **Bacterial diseases,** 12–15.
Bacteriophage, 7 (2).
Baldness, 53 (1).
Barber's rash, 54 (1).
Barbiturates, 23 (2).
Bell's palsy, 50 (2).
Benzedrine. The proprietary name of a dru known as amphetamine. *See* 23 (2).
Beri-beri, 43 (1).
Bilharzia, 18 (2), 16 (1).
Birth control, 57 (2).
Blackwater fever, 17 (2).
Bladder. *See under* **Urinary diseases,** 45 (1).
Bleeding diseases, 26 (1).
Blepharitis, 55 (2).
Blood, function of the, 24.
Blood, diseases of the, 24.
Blood poisoning (septicæmia), 14 (2).
Blood-pressure, 29.
Blood-vessels, diseases of the, 30.
Blue babies, 5 (2).
Boils. A boil is an infection of the skin, and caused by three separate factors: (1) th presence of germs on the surface of the skin (2) lowered bodily resistance to these particula germs; and (3) the existence of pressure friction causing the germs to be rubbed int small cracks in the skin. Boils are therefor commonest where such pressure exists, *e.g.*, o the neck where the collar rubs, on the wrist beneath the cuffs, in the armpit, and on th buttocks. The treatment is directed to th causes: (1) keep the skin clean with frequen washing with soap and water; (2) increas bodily resistance by taking yeast tablets; (avoid pressure and friction, and ensure tha collars and other clothing compressing the ski are frequently changed. It should not b forgotten that, when many boils occur, thi may be a sign of diabetes or other chronic disease.
Botulism, 14 (1).
Brain. *See under* **Nervous system,** 46–7, **Physica injuries,** 19, **Undernutrition,** 58.
Brain abscess, 47 (2).
Brain tumour, 47 (2).
Breasts, 56 (1).
Bronchiectasis, 32 (2).
Bronchitis, 32(2).
Bruises and abrasions, 19 (2).
Bürger's disease, 31 (1).
Burns and scalds, 21 (2).

Cachexia. Extreme wasting due to disease.
Cæsarean operation. When the abdomen has t be opened to remove the child, named aft Julius Cæsar, who is said to have been born this way.
Caisson disease (decompression sickness), 31 (1)
Cancer of the breast, 56 (2).
Cancer of the cervix, 56 (2).
Cancer of the lung, 33 (2).
Cancer of the œsophagus, 35 (1).

er of the rectum, 38 (2).
er of the stomach, 35 (2).
er test (cervical smear), 56 (2).
ohydrates. The scientific name for sugars,
rches, and cellulose, 40 (2).
on monoxide poisoning, 21 (1).
uncle. A large boil.
ac neurosis, 27 (1).
act, 56 (1).
wick, Sir Edwin (1800–90). English social
ormer, 6.
croid, 16 (1).
ge of life, 57 (1).
enpox, 10 (1).
ains, 53 (2).
This is not a proper medical word, but
ers to the symptoms that occur when one
t becomes infected with any germs which
se fever. When such germs enter the body,
the defending processes are mobilised and
eded up. The white cells in the blood in-
ase in number, and the amount of energy
d is greater than normal, causing the tem-
ature to rise. This rise in temperature
reases the ability of the body to fight back,
, in order to retain heat within the body, the
od-vessels in the skin contract so that less
t is lost by radiation. This makes the skin
l and pale. What is ordinarily called a chill
nerely an infection by the germs causing cold
influenza. But a chill may be the pre-
inary to almost any infectious disease, such
measles, mumps, scarlet fever, pneumonia,
so on. The best treatment when the tem-
ature is raised is to go to bed with as much
mth as possible. Hot drinks and hot-water
cles are helpful. *See* **Colds,** 10 (2), 31 (2).

Gingivitis. Inflammation of the gums due to infection and requiring treatment by a dentist.
Glands. There are three main types of glands. (1) lymph glands, which are found mainly at various junctions in the body, such as the armpit (where the arm joins the chest), in the groin (where the leg joins the pelvis), and also within the body and around the base of the neck. Their function is to trap germs and prevent them reaching vital areas. That is why in an infection of hand or foot a swelling often develops in the groin or armpit—the glands having trapped the germs are themselves suffering from inflammation; (2) larger glands, such as the pancreas and liver which produce mainly digestive agents such as bile, trypsin, and so on. These glands empty their products into the intestines through a duct or tube; (3) the endocrine glands, which are also called ductless glands because they empty their products direct into the blood-stream, and unlike the former have no ducts. These glands are of immense importance because they have a great deal to do with making an individual into the type of personality that he is. The best-known endocrine gland is the thyroid in the base of the neck, which acts as accelerator to the body. That is, it controls the speed at which body processes are carried out. When it is over-active (*see* **Goitre**) the patient becomes tense, nervous, flushed, his heart beats faster, and he loses weight. If the gland is too sluggish in action, the effect is the opposite (*see* **Myxœdema**). The small parathyroid glands, attached to the thyroid, control the amount of calcium in the blood, and therefore are also related to nervous tension, and, in addition, to the constitution of the bones. The sex glands, ovary in women and testis in men, produce the typical sexual characters of the adult, while the suprarenal glands prepare the body for emergencies, for example, by producing the emotion of fear. All these glands are coordinated by the pituitary gland at the base of the brain, which, besides controlling the other glands, determines the height of the individual, his self-assertiveness or otherwise, and many other personality traits. In addition to the above, the pancreas which supplies through a duct digestive ferments into the intestines, also produces insulin (*see* **Diabetes**) which passes directly into the blood.

Pleurisy. The lining of the chest wall, which also forms a covering for the lungs, is known as the pleura. When this becomes inflamed, the illness is called pleurisy. Pleurisy is almost always due to infection with a germ, and most often occurs in the course of another illness, such as measles, scarlet fever, tuberculosis, abscess, or sometimes following a blow to the chest. In the early stage, inflammation causes friction between the two layers of pleura, and this causes pain, but later fluid is secreted, and "pleurisy with effusion" results. Treatment in mild cases is mainly a matter of rest, but when fluid has formed it may be necessary to withdraw this with a needle or even by a surgical operation. Nowadays, penicillin or the sulphonamide drugs can be used. The commonest symptoms of pleurisy are pain in the chest, cough, and fever. When fluid has formed, the pain tends to disappear.

Psychosomatic diseases. Psychosomatic diseases are those physical ailments due to emotional causes. They include such complaints as high blood-pressure, gastric ulcer, certain skin diseases, and certain glandular diseases (*e.g.*, exophthalmic goitre). Most physicians nowadays believe that all diseases may show a greater or less degree of emotional causation; that physical and mental factors are both present in all illness. Even in psychosomatic illnesses, heredity and other factors play a large part. Briefly, the main cause of these diseases is worry. The importance of this lies in the fact that they cannot be cured without dealing with the fundamental cause. *See also* New Views on Medicine, 3 (2). Individual illnesses will be found under their names.

Conclusions 28

HUMAN RELATIONS

iis section we have tried to give the reader an understanding of modern society and of the forces h motivate behaviour so that he can interpret what is going on around him and in his own mind. ffort has also been made to provide that help which understanding alone can give not only in the ting out of one's own problems but in extending tolerance towards the shortcomings of others.

ie section is in three parts:

I. The Self (i.e., the individual and his development and the way he meets the problems of life in the process of growing up).

II. Society (i.e., our relationships with other people from the family to the larger social groups and the problems created by changing social patterns).

III. Work (i.e., all the many factors that affect the worker in an industrial society).

iese categories overlap to some extent since we are not isolated individuals but involved with le from the earliest days, and work is an integral part of everyone's life, so each part flows into the , occasionally making a little repetition inevitable.

INTRODUCTION.

l societies have had their problems and their s of crisis and modern society is no exception. t is special about our problems is that they of an entirely different nature from those h faced our forefathers. For them, as over areas of the earth even today, the main rds came from an untamed natural environ- t in which plagues were rampant and malnutri- the rule, in which crops and livestock could avaged by adverse weather or disease, bring- starvation and death just as surely as the ues afflicting man himself. This is still the of affairs in many of the technically under- loped countries of the world where epidemic ases, chronic infections such as malaria and rculosis, hunger, poverty, and malnutrition need immediate action. To improve the an environment calls for efforts by the nunity as a whole which these poorer coun- are, as yet, incapable of making by them- s, for their people have neither the necessary vledge, wealth, nor organisation to do so, and, difficult of all, they need to change long- plished habits and attitudes.

ie peoples of the Western countries have so ified their environment that they have suc- ed in adding many years to their average ctation of life, yet it is not so long ago that had to face similar problems. For ex- e, it is little more than a hundred years ago 8), when the appalling living conditions re- ng from the industrial revolution threatened pread disease throughout Britain, that the public health measures were taken to deal the fearful cholera and smallpox epidemics h were then prevalent. In Ireland, failure of otato crop led to the great famine of the 1840s a million people died of starvation and a on and a quarter were forced to emigrate. ng the influenza epidemic which followed the World War more people died in a single year were killed on all the fronts in four years of stating war. In 1962 only 882 cases of ria were detected among 648 million people urope (including Russia) compared with 10 on at the end of the Second World War. The ctation of life in Britain has increased by 25 since the turn of the century: a baby boy now expect to live to 68 years and a girl to 74. process which began gradually about a red years ago and accelerated in recent times it has become an explosion, our circumstances radically changed as technology has advanced and along with the truly wonderful scientific achievements of our civilisation have come new and unheralded dangers. We are living largely in a synthetic environment created by our own technology and our most serious problems today are caused not by nature but by ourselves. This is perhaps a depressing fact, but it is also a hopeful one; for we are now at little risk from the physical world around us and it might be thought that the minds which created the new environment are surely capable of solving the problems which come in its wake.

Unfortunately the situation is not quite so simple because, though we know a good deal about the physical universe and how to bring it under control, we know rather less about ourselves and what information is available does not suggest that human problems are as easy to solve as technical ones. Most of us are able to handle things with some measure of efficiency, but we are likely to be much less skilled when it comes to human relationships and, in the long run, even things become tied up with personal emotions. Thus there are not *two* sets of problems, the one concerned with science and technology and the other with mental life, because science and technology *in themselves* create no problems at all—there is really only one problem and that is the uses to which we put our knowledge. Man uses his reason to find out about the physical universe but all too often what he does with his discoveries is determined not by reason but by false beliefs, old traditions, and emotional prejudice.

Among the major problems in the world today are racial and national hatred, undernourishment, over-population, the control of disease in impoverished countries, the prevention of nuclear war, superstition, illiteracy and poor educational standards. Most of the causes of these are already known and in many cases the remedies are not only known but capable of being put into practice immediately. What stops them from being effectively dealt with is not lack of knowledge but the fact that we are unable to understand or control ourselves; the problems are not outside but inside man—his stupidity, greed, aggressiveness, suspicions and prejudices. These are the concern of the psychologist, because psychology is the scientific study of human behaviour, emotions, and thoughts. In the pages that follow we shall be dealing mainly with those aspects of the subject which are most relevant to the individual citizen in the Western world today but it is hoped that the reader will gain some insight into the forces which motivate all men irrespective of politics, race, or creed.

Adjusting to Inevitable Change.

Broadly speaking, the problems of the West are those of the Welfare State or what has been described as the Affluent Society (the two are not quite the same because, though a welfare state may be affluent, an affluent society like America is certainly not a welfare state). Along with very real benefits such as comparative economic security, improved material well-being, freedom from many of the killing diseases which once plagued us, greater social mobility, and better opportunities for higher education, have come other features which cannot be cured by more affluence. Many people are bored, rebellious, perplexed, and downright unhappy, and some would ascribe this to the 'spiritual sickness of our time' brought about by the loss of traditional values. Perhaps they are right. The only trouble about this analysis is that it is not a very helpful approach because traditional values ca not be brought back by legislation, nor is it d sirable that they should be brought back at a Our real problem is that we have failed to adju to a rapidly-changing technological environmen which demands a new set of values and fre attitudes. More than a century and a half ago famous philosopher wrote that "man, insofar he acts to change his environment, acts to chan himself," and herein lies our failure; we ha created a new environment but have failed make new adjustments to it though the essence normality is the ability to see and react appr priately to life as it is. The authoritarian fami has gone, woman's place in relation to home a work has changed, traditional attitudes in i dustry are dying, and the gulf in understandi between parents and children has increased b cause the pre-war world is not the world of toda All these issues will be discussed here.

I. THE SELF

1. THE FOUNDATIONS.

What is Personality?

Personality may be defined as that arrangement of traits which are relatively consistent and enduring attributes of an individual's behaviour. Thus if one man is aggressive in any and every situation and another gentle and thoughtful towards everyone he meets, then we are entitled to assume that these are fundamental and relatively fixed aspects of their personalities.

On the other hand, it is easy to see that whilst some aspects of behaviour are comparatively stable, people's actions are also variable—they may be shy in one set of circumstances and not in another, dominating within one group and submissive elsewhere. This is because these traits are not something *in* the individual, but are simply a response to the social circumstances he is facing at the moment. In more technical terms, they are not a function of his personality but rather a function of the role he is playing as a member of a group facing a specific situation.

So it often happens that we attribute certain characteristics of a person to his innate traits when, in fact, they only appear to be fixed because we always meet him in the same social surroundings. For example, a supervisor in a factory who finds that one of his workers is always resentful is liable to suppose that he is just resentful by nature, whereas, if he saw the man at home he might be surprised to discover that his family and neighbours regard him as kindly and generous to a fault. The reason is, of course, that the worker is resentful in response to the factory situation which, being the kind of person he is, he finds frustrating because it does not permit free expression to his real abilities. Thus what might be described as the 'core' personality is rigid in structure and resists change, whilst the more superficial aspects of personality, of which the above is an instance, change very rapidly as the individual moves from one group to another, and these aspects are described as relating to the 'peripheral', 'public', or 'social' personality. The practical significance of this distinction will be seen later, but it is obvious that if we are dealing with a social problem such as juvenile delinquency it is absolutely necessary to know whether, in a given case, we are faced with an attitude which is firmly ingrained in the youth or whether he is simply responding to a frustrating environment.

Some aspects of personality are therefore relatively fixed whilst others merely reflect responses to a particular environment, but the two cannot be entirely separated because most of the time people tend to respond, not to the environment as it really is but *to the environment as they interpret it* and this naturally depends upon the nature of their core personality. In the example of the worker quoted above, it is obvious that he was suspicious, not merely because of the objective situation (which of course first aroused his suspicions) but because he was the sort of person who might be expected to feel that way in those circumstances. Perhaps his innate intelligence and the fact that he had been brought up with the ambition to better himself made the situation mo intolerable to him than to his mates (though some factories things may be so bad that near everyone feels dissatisfied). But this does n alter the fact that a change to a more satisfyi job would change the behaviour of this particul man, whilst, in other cases, suspiciousness may an ingrained trait which appears in any situatio

How is Personality Fashioned?

Where, then, do these fixed traits come fro Broadly speaking, they arise from three distin but interacting sources: temperament, the chil rearing patterns of the first five or six years of lif and the culture in which the individual is broug up. Temperament is what we inherit, and chil rearing patterns are based on the way in whi the parents attempt to pass on the culture to whi they and their children belong. The family, it h been said, is the personality-factory of socie which attempts with greater or lesser success inculcate the ideals of a particular group in each new generation. To use another metaph we come into the world as an undifferentiat lump of clay which nevertheless has its ow particular properties, the family is the potter, a culture supplies the design. If our society valu conquest, we shall be brought up to admire a try to emulate war-like men; if it measures su cess in terms of money we shall see acquisitiven and wealth as our goal; and, in a caste societ we must learn to behave in all ways according the position into which we are born. This ide pattern is the *basic personality structure* and r presents those aspects of personality which di tinguish the members of one cultural group fro another and defines what is considered 'normal' in a given society. The variations this common theme which differentiate o member of the group from any other memb making him, to some extent, a unique individu are what is described as 'character'. Since t interplay between these various factors is ve subtle, it is necessary to discuss them in mo detail.

Temperament.

Just a century ago the Austrian monk Greg Mendel was able to show that the physic characteristics of plants are passed on from o generation to the next according to certain defini laws (*see* **Section F, Part II**). It is known th such factors as body-build, hair and eye colou height, and the rest are inherited in this way, a there are a few diseases (probably not more tha can be counted on the fingers of one hand) such hæmophilia, which are also known to be heredi ary. But when it comes to mental traits, we a on much less secure ground, largely because it difficult to distinguish between what has been i herited and what has been learnt. Nearly psychologists believe that if a son is fussy a punctilious like his father this is because he h been taught to behave in this way or has learn it by imitation, and whilst many psychiatris (*i.e.*, physicians who specialise in treating ment

rders) believe that a *tendency* to certain forms
isanity is inherited, few would accept that this
rue of the minor forms of neurosis. It is
wn for certain that general intelligence is de-
ined at the moment of conception, and quite
y that the traits collectively described as
nperament ' are largely inherited because they
n to be correlated with body-build. The short
ky individual with a tendency to run to fat is
ally cheerful and outgoing—one of those de-
bed by Shakespeare when he referred to " men
: are fat, sleek-headed men and such as sleep
ghts " and compared them to Cassius with his
an and hungry look " who " thinks too much—
n men are dangerous ". The former type of
y-build is the ' pyknic ' and his temperament
cyclothyme ' or ' extraverted ', the latter has
æsthenic ' build associated with a ' schizoid '
' introverted ' temperament. (*See also*
racterology, **J8**.)

Interplay of Heredity and Environment.

ut all this has to be modified because the intro-
and extravert are obviously at the extreme
of a normal curve of distribution so most
ole fall in between the two and both attitudes
be considerably modified by cultural factors.
extravert, who would naturally be given to
ativeness and the strong expression of his
tions, if born into a Red Indian tribe, where
approved basic personality structure is the
assive and silent man, would become just as
assive as the rest. Even intelligence, the only
tal trait which we know *for certain* to be in-
ced, can be considerably modified by environ-
tal factors which encourage or discourage its
development. Furthermore, there are two
r considerations to be taken into account:
not every trait that a child is born with is
rited, and second, heredity may have an
rect as well as a direct effect on character.
t a child is born with is congenital, but con-
tal traits are not always inherited or de-
ined at the moment of conception; for we
v that what takes place whilst the child is de-
oing within the womb also has a potent in-
ce on its future life, usually for the worse.
s German measles in the mother, birth injury,
drugs such as thalidomide taken in the early
s of pregnancy (*see* **P4**) can cause severe
tal defect or physical deformity. Again, the
t of inherited characteristics may be indirect
nding upon how they are regarded by the
ty into which the child is born and the way
child reacts to the views of his society. For
nple, a mentally-retarded or brain-damaged
on may be regarded with contempt or pity in
group or be thrust into a position of high
s as a witch-doctor or sorcerer in another.
y who is short in stature may become neurotic
a failure when he is teased by his associates
n the other hand, may compensate by be-
ng powerful and dominating to cover up his
iency. The influence of heredity is therefore
complex and even the most fixed traits may
nsiderably modified by environment; stature
herited, but without adequate diet the full
re will not be reached, whereas given better
ishment it will. The youth of Britain today
n the average considerably taller than their
dparents, and the Japanese who were always
ded as ' naturally ' small are becoming taller
e economic position of their country improves.
dity, by and large, does not determine the
is—it merely sets the limits.

-rearing Patterns.

Follows that, though we are prone to think of
hild as a pre-fabricated structure waiting at
to be erected, for better or worse, by the
s who look after it, this is a wholly mistaken
, because *prior to an infant's earliest contacts*
other human beings it simply does not exist as a
on ' at all. All we have is a living thing
certain physical characteristics, a *potential*
ectual level which, again, without the inter-
on of people could not raise him above the
of an idiot or a chimpanzee, and a bundle of
ical drives such as hunger, thirst, sex, and
eeds for sleep and warmth which only others
atisfy. Human beings are unlike animals in
their prolonged period of helplessness, in their ability to communicate by speech, in the possession of an opposable thumb which makes it possible to carry out delicate manipulations, in the fact that they alone can hand on knowledge or culture from one generation to the next and, above all, in having no instincts. Correctly used, the word ' instinct ' refers to behaviour inherited in the structure of the nervous system, unlearned, and relatively unmodifiable; it is typical of the lower animals which automatically carry out quite complicated actions such as nest-building, yearly migrations, courting behaviour, and so on, without having been taught how to do so. In the higher animals such as apes this is already a disappearing category and, so far as human beings are concerned, it has disappeared altogether, being replaced by undifferentiated drives or needs that are inherited, but require the help of a family before they develop into the patterns for satisfying them approved in a given society.

The Sense of Self.

The need for food like the need for sleep, is innate but from a very early age the child learns not merely to demand food or sleep as such, but certain kinds of food and certain hours of sleep which it has been taught are ' right ' and ' good '. The basic psychological process occurs in a particular direction: the infant has physical needs which demand satisfaction, it becomes aware of the world around it, interprets it, responds to it, finally responds to the results of its own response. It feels sensations of hunger, becomes aware of the breast, interprets it as a source of food, sucks it, and depending upon whether its experience is satisfying or not, feels pleasure, anger, or anxiety. Because the way in which people or things respond to our approaches to them influences our attitude towards ourselves, it has been said that the self is based on " the reflected appraisal of other people ", or more dramatically by an Italian novelist, that " the self is the meeting-place of all relationships ". In other words, we do not just *have* experiences, we *are* our experiences and in later life we treat others as we interpret the way they treated us during the formative years, and value or dislike ourselves as we believe we were valued or otherwise. This too is important in understanding certain types of delinquency, because one can only give as much love as one has received, and a delinquent who has suffered from parental neglect may become what is known as a ' loveless character ' because he literally has no love to give and can only respond with hate. The selfish person does not care for others, but he does not care for himself either.

2. THE FORMATIVE YEARS.

The Fundamental Need for Love and Protection.

The biological needs of hunger, thirst, and the rest, by reason of the utter helplessness of the human infant, cannot be satisfied unaided, so there arises very early in life the most fundamental of psychological needs—the need to be loved, protected, and cared for. Love is not something we are born with; it develops through a series of stages from mere cupboard love to a mature and disinterested affection for other people. Hate is an emotion which arises when certain needs are frustrated—in fact, it might almost be said to be a derivative of love since, together with anxiety, it is initially aroused by fear of loss of love. This need to be cared for leads in later life to the need for personal affection and subsequently to a desire for the approval of society so, as one psychologist puts it, love forms " the underpinning on which all the later motives and the cultural imperatives are constructed ".

The Formation of Basic Attitudes.

During the first five years of life the child begins to learn, not only by the process of conditioning whereby it comes to associate two quite different stimuli together as a dog learns to associate the the sound of a whistle with food because one has always followed the other, whilst ignoring the sound of a bell which has been unrelated to food, but also by a process of trial and error and by imitating its parents. Habits are established by differential reward and punishment, indulgence and deprivation, or the implied threat of deprivation of affection on the part of the parents who make use of the infant's needs to avoid harm and obtain approval and the satisfaction of its biological drives to this end. The habits acquired at this stage relate to sleeping and feeding, bowel and bladder control and the child's early loves and hates (Œdipus complex) within the family circle. Throughout this period it develops attitudes towards its father and mother, brothers and sisters, which becomes the model of its attitudes towards all the people it meets subsequently. So, whilst the core personality is being laid down, the child is not only learning control of its excretory and feeding functions but also how to deal with people; if it is not given affection freely, consistently, and unconditionally, it will soon discover more devious ways of getting attention. If being sick produces the required results, the child will grow up into the sort of person who tries to get affection by taking refuge in real or imaginary illnesses when trouble threatens. If keeping to oneself works ("If I leave people alone they won't harm me"), he will be unsociable, and if a domineering or aggressive attitude works that is what he will become. Naughty and ultimately delinquent behaviour sometimes arises from the child's feeling that he is not cared for ("All right, if you don't love me, at least I'll see to it that you have to give me *some* sort of attention")

The important point is that all our most basic attitudes arise because at one time they demonstrably worked. As a child psychiatrist expresses it: "We become acceptable or non-acceptable, helpless or capable, important or insignificant, passive or aggressive, busy or lazy, resourceful, or cautious, or sweet, or clever, or polite, or thoughtful, or obedient, or demanding, or a thousand and one other characteristics. These are the traits which are produced by the child and structuralised into his very self because of their *functional* value to him in the earliest years of life. Each one was the trait that worked best and got the best results in the particular setting in which he was placed."

How the Personality Develops.

Parents usually think of child-rearing as a simple—or at least theoretically simple—and direct process whereby 'good' behaviour is inculcated and 'bad' behaviour discouraged by reward and punishment, personal example, and later by speech. Unfortunately this is not the case because, though these are important, other facts must be taken into consideration. To begin with, character formation starts from the very earliest weeks and those traits which are learned then are the most potent by reason of the Law of Primacy which states that the earlier an experience the greater its effect. This is because from birth onwards the way we interpret a new experience depends on our previous mental state; for example, though a child will certainly have no conscious memory of satisfying or unsatisfying emotions at the breast, these are nevertheless built into its brain structure and cause it to see later events in a hopeful or depressing light.

Early Infancy.

There is very good evidence that in the first six months of infancy we have already acquired basic traits which make for an authoritarian or humanitarian outlook and, in fact, the words of the song by Gilbert and Sullivan to the effect that "every boy and every girl that's born into this world alive is either a little Liberal or else a little Conservative" are quite literally true with the single modification that we are not born that way but learn these attitudes at the breast. Of course, like the introvert–extravert scale and the level of intelligence, these attitudes are distributed over a normal curve so that most people fall somewhere about the middle, and the radical-conservative scale is not meant to refer to any political party, though it will clearly influence later political beliefs.

Again, it is almost certain that such traits a fussiness, punctuality, belief in discipline, ex cessive concern with cleanliness, and extrem (but repressed) aggressiveness are learned, no by direct example, but are intercorrelate attitudes associated with an over-strict emphasi on bowel training. Those nations which valu punctiliousness, obedience, and strict hygien (*e.g.*, the Teutonic nations) are also likely to b aggressive, obsessed with bowel functions (*c.f* Martin Luther), and to make jokes, not as i other countries about sex, but about lavatories.

The Beginnings of Conscience.

At a later stage, about the age of five or six, th child normally passes through what is known a the Œdipus complex when it loves the parent o the opposite sex and feels correspondingly jealou of the parent of the same sex as a rival and thi influences its attitudes towards the opposite se throughout life. But quite soon it begins to re alise the futility of this state of affairs and fro then on two important things happen. Firs the child leaves behind the stage when its mora controls came from outside, from the orders of it parents, and by a process known as 'introjection takes the parent's moral attitudes inside itsel This is the earliest beginnings of the adult co science which initially starts as an 'internalise parent' exercising control from within instead o having it superimposed from without. Second the child now begins to imitate the parent of th *same* sex, and in this way the boy learns how t play the masculine role as defined in his society the girl to play the feminine role. This is a ver important stage and in households where th father is absent, badly behaved, or a weakling the boy may imitate his mother and develo homosexual tendencies in later life.

Child–Parent Relationship.

There are therefore two parallel processes in volved in child-rearing, the one conscious an deliberate in which the child is taught to behav according to the rules of its society and also learn in the academic sense, but the more significan one is an unconscious process because, as we hav seen, many of our most deep-rooted traits aris during the period when the child cannot unde stand speech and are the result of an interactio between parent and child at a time when th parent is unlikely to realise the values he or she i actually inculcating. In short, the child is res ponding more to what his parents *are* than to wha they *say*, and therefore *the basic rule in bringin up a child is to give it unconditional, secure, an consistent affection.* But it is only the norma parent who is able to do this and, since not man of us have reached full emotional maturity, ou children may appear to be getting plenty o affection, but the true reasons for the mother behaviour may be guilt at not feeling enough lov or, if she is unhappy with her husband, she ma be displacing her frustrated affections on her son– in neither case is the love healthy or genuine an the child will suffer.

Even the formal educational process is influen ced by these emotional undercurrents which th parents neither understand nor are capable o controlling, and the child will accept or rejec what it is deliberately taught, not in terms of it truth or real value, but rather in terms of h unconscious (or sometimes conscious) feeling towards the parent who tries to inculcate them The boy who either unconsciously resents h father or is striving to become independent o unduly possessive parents (or even, as sometim happens, trying to avoid being overwhelmed b the reputation of a well-loved but very famou father) is more likely to reject his father's religiou philosophical, or political views than to accep them. One little boy whose very tolerant paren had never uttered a word of condemnatio against his lack of interest in books were distresse to hear him say when he thought they were no listening, "Of course, I'm the idiot of the family —they had *said* nothing, but the walls of the home covered with bookshelves filled with book many of which they themselves had written, ha said a great deal. The boy excelled at getting o with his schoolmates and at sport, but until th

ons for his attitude against learning were
nted out to him, he did not do well academi-
y. Once he had learned what was going on
his unconscious, he became one of the best
olars in his college.

3. THE UNCONSCIOUS PROCESSES SHAPING PERSONALITY

Repression of Emotions.

n general, we only pay attention to those
nents of our environment which (*a*) fit in with
rest of our beliefs, and (*b*) help to further the
ion in hand at the moment. Freud, the foun-
of psychoanalysis, pointed out that all those
otions and thoughts which are repugnant to
individual are either pushed into his uncon-
ous or never allowed to leave it. They are, as
ud said, "repressed"—a term which does
mean the conscious *suppression* of anti-
ial desires, but the refusal even to recognise
ir existence. (*See also* **Freudian Theory,**
tion F, Part III.) However, as others have
nted out since, it is not only those aspects of
sonality which are regarded as morally objec-
nable that come to be repressed, but traits
ch, whilst not necessarily 'bad' in themselves,
not fit in with conscious attitudes. Charles
rwin, for example, admitted that, as he became
re and more absorbed in reasoning and scientific
suits, he lost the ability to enjoy, as he once
done, the pleasures of poetry and literature.
shall see later that one of the great barriers to
nging attitudes from whatever motive is the
that, after they have grown up, people do not
l to seek new experiences but rather to rein-
e existing prejudices.

or the moment, however, we are concerned
h those emotions and desires which are re-
ssed in the original Freudian sense. When
n emotions are repressed they do not cease to
t and sometimes have quite devastating effects
the individual and his associates. Thus those
have been brought up to refuse to recognise
r aggressiveness may repress it and, by the
cess known as 'reaction-formation', become
pulsively 'gentle'. Their assumed 'gentle-
s' is adopted in order to fight their 'bad'
ressive side; and so we often find (and this is
tragedy of these movements) that those who
pacifists, vegetarians, and against cruelty to
nals or children cannot help their latent
ressiveness from leaking out. This leads to
n unpleasant phenomena as the obvious ten-
cy to fragmentation and quarrelsomeness
hin pacifist movements, an unhealthy absorp-
in cruelty quite frequently in situations where
ers see none, and extreme intolerance. Jung
cribed this unrecognised aspect of a man's
ure as his "shadow", giving as an example a
n he had once met, a Quaker, who could not
gine that he had ever done anything wrong in
life. "And do you know what happened to
children?" Jung asked. "The son became a
f, and the daughter a prostitute. Because the
er would not take on his shadow, his share in
imperfection of human nature, his children
e compelled to live out the dark side which he
ignored." Thus unconscious attitudes in the
nts are sometimes more potent in influencing
r children than the respectable conscious ones.

tal Mechanisms to Guard Our Self-Esteem.

nce everyone has had to repress quite a lot of
ceptable material (and, of course, the indivi-
has been *taught* to reject it though it may be
nless enough in itself and infinitely more
gerous repressed than openly recognised), the
l has learned many tricks for concealing those
s or memories from awareness. These forms
elf-deception are what Freud described as
ental mechanisms" which permit some form
xpression without allowing knowledge of its
ce. These are explained under **Freudian**
ory, Section F, Part III. The lesson to be
ned is that the proper way of dealing with
essed emotions is (*a*) to recognise them, and
to sublimate them—*i.e.*, *consciously* direct
towards socially useful ends. Many who
helped the poor and sick have been stimula-
o do so because of their own unhappy child-
hood experiences and those who have done something useful on behalf of small underprivileged nations or classes have usually been well aware that it was their own early experience of being underprivileged that caused them to do so.

The Nature of Aggression.

Hardly any subject in the whole field of psychology is more important than the problem of aggression, and it is doubtful if any is less understood by the layman. This is little short of tragic since it is obvious that what is generally comprehended under the name of aggression is responsible for many of the issues facing us today: for example, warfare between nations, crimes of violence, race prejudice, and the concern felt by many about violence on television or in children's 'comics', all reflect the necessity for taking the matter seriously. What stands in the way of genuine understanding is the fact that, as is so often the case in psychology, most people are not only convinced that they already know all that needs to be known but, worse still, they are confident that they know the solutions. What could be more apparent than that war is caused by the 'instinct' of aggression, that violent crimes can be cured by violence, or that horror scenes in comics or on television are a cause of juvenile delinquency which can therefore be reduced by preventing children from being exposed to them? Naturally enough, anyone who is rash enough to attempt to show that these are dangerous delusions or that, to say the least, the problem is much more complex than is often supposed, is immediately suspect of blinding himself to realities or of being 'soft' when the correct attitude is to be 'hard' and 'objective'. However, the reader is invited to try to see the other side of the picture.

Life Energy or Drive.

In the first place, 'aggression' is not a simple entity synonymous with 'hate', and this confusion leads to the belief that what is a perfectly natural and inborn tendency is, without qualification, evil. Actually, as Dr. D. W. Winnicott, who is one of the most eminent British psychoanalysts (*i.e.*, those who treat patients by the methods based on the theories of Freud) has pointed out, "at origin aggressiveness is almost synonymous with activity". It is not an 'instinct' nor even a specific drive but the natural tendency to overcome obstacles to the attainment of goals without which life itself could not exist; thus we talk about 'attacking' a problem, 'struggling with' and 'overcoming' a difficulty, 'mastering' a subject or 'getting one's teeth into it'.

Hate or Anger.

In this sense aggressiveness is simply life-energy which, when it meets a barrier to satisfaction (whether the need for satisfaction involves solving a mental problem or looking for one's next meal) accumulates in order to summon up enough power to overcome it. This sort of behaviour is happening to everybody at every hour of the day and usually the barrier is successfully overcome and the organism returns briefly to the original resting state. But if it proves insurmountable, a state of frustration develops which leads to emotions which can be described as 'aggression' in the more limited sense of the word implying anger, anxiety, and hate. Hate arises in interpersonal situations, that is to say, it is something we feel towards *people*, arising originally from fear of loss of love which threatened our security in infancy because an unloving mother could not be relied upon to satisfy our physical needs, and subsequently it arises in situations where security is threatened either in the emotional sense or when there exists a real or imagined physical danger to status, life, or property. For example, rejection in love threatens our self-image by damaging that personal esteem which is the badge of psychological security, and the fear of attack from other individuals, groups, or nations threatens our physical security, so both are prone to lead to hate. *Since hatred is so closely linked with anxiety, anxious and insecure people are particularly prone to irrational hatred.* Thus revolutions are not made by the secure ruling classes who have nothing to gain, nor (as the Communists have learned to their cost) by the very poor who have nothing to lose, but by the insecure lower middle classes; those who incite race riots in the southern states of America are not the well-to-do or the old 'aristocracy' who are often, in private, quite liberal in their views, but the 'poor whites' whose only claim to superiority rests on their colour. Anger, though often directed against people, is also aroused by situations or things which frustrate the individual, such as the car that fails to start; hate always involves people, anger does not.

How Aggression is Dealt With.

When a great deal of anger or hatred (*i.e.*, aggression in the narrower sense of the word) has been aroused, various possibilities of handling it arise. The normal reaction is to assess the situation rationally and consciously recognise one's feelings for what they are; from this point one may feel that by an increased effort the barrier to satisfaction may be overcome and decide to carry on, or that the barrier is genuinely insuperable so that further effort would be wasted and that, failure being no disgrace in the circumstances, one can without loss of self-respect redirect one's efforts elsewhere. Unfortunately, in our own culture children are often brought up to believe that anger, aggression, or even normal self-assertion are 'bad' emotions to be suppressed just as much as 'evil' sexual desires. When this happens, what was once consciously suppressed by the threat of punishment or loss of love in childhood soon comes to be automatically and unconsciously repressed in later life. In this case our aggressive feelings (which, as mentioned above, may sometimes extend to what is merely self-assertiveness or the right to develop oneself as an independent individual) are dealt with by *denial*—we deny that they exist at all, or assert that they exist in other people but not in ourselves, or direct them against a socially-accepted scapegoat. That is to say, they are repressed, projected, or displaced, and this is the cause of most of the troubles facing the modern world. Those who lead campaigns for peace, if in many cases genuinely gentle people or motivated by a commonsense realisation that the human race must choose between international peace or total destruction, are all too frequently individuals who are compulsively 'gentle' in a neurotic attempt to deny their own destructive tendencies. But the denial of such tendencies does not prevent their manifesting themselves in such a way as to frustrate the achievement of the avowed goals of the movement and, to quote Dr. Winnicott once more: "*If society is in danger, it is not because of man's aggressiveness, but because of the repression of personal aggressiveness in individuals.*"

The Effects of Repressing Aggressive Feelings.

Normal sexual or aggressive feelings when denied give rise to those horrible sexual and aggressive fantasies which, when projected upon the outer world, lead to that race hatred when the victim of what is in fact a diseased imagination pictures his womenfolk being raped by Negroes or himself being dominated by designing Jews. The problem of war will be discussed elsewhere, but it is worth while noting here that one of the main reasons why warfare occurs is that for masses of frustrated people it is the most obvious way out of their frustrations; in fact, if we do not exactly *want* wars there are millions who *need* them. Freud pointed out the apparent paradox that a nation is never so much at peace within itself as when it is fighting an external enemy, from which it follows that countries which have long been living peacefully with their neighbours will have more aggression to direct inwardly. That this contains more than a grain of truth is evinced by the high suicide rate in such countries as Sweden and Switzerland, and Jung, himself a Swiss, referring to the peculiar bitterness of Swiss internal politics, made the remark that his people had "introverted war".

But there are some people in whom any self-assertive or aggressive manifestations have been so thoroughly repressed that they are permitted hardly any expression even in the forms described above; such individuals are as embarrassed and anxious at the least sign of anger or self-assertion in quite normal circumstances as the prude i upset by things with a sexual connotation which the ordinary person simply does not notice When this occurs the only possible solution is t *introject* the aggression (*i.e.*, turn it against the self), and this leads to severe states of depression—which is really self-hatred—to actual suicide, o to psychosomatic disorders such as high blood pressure brought about by prolonged stress Finally, it must be remembered that suicide is no the only form of self-destruction, that chroni alcoholism, drug addiction, accident-proneness and other conditions are often unconsciou attempts to walk slowly or rapidly along the roa to death and failure, resulting from inwardly directed aggression. These are, of course, state that *may* be brought about by introjection, thoug since different people have different levels o tolerance and stamina they do not invariably occur; what we can safely say is that, as aggression in its original aspect is a manifestation of the drive towards self-assertion and self-realisation, it repression will *inevitably* lead to impoverishmen and inadequacy of the personality.

4. THE FIVE AGES OF MAN.

Disregarding Shakespeare's account of th seven ages of man, we shall describe for the sak of convenience a mere five: childhood, adolescence, the period during which we can still hopefully expect to be described as a young bachelo or married couple, middle age, and old age. Each of these age groups has its own special problems so it is necessary to observe the process of development and the satisfactions and difficulties arisin at each stage whilst remembering that many, i not most, of these difficulties arise in a socia context and cannot be usefully considered i terms of the non-existent isolated individual For example, though we in the West commonl (and not without justice) regard adolescence as period of 'storm and stress', this is not the cas in other societies, and therefore must be regarde as a socially-conditioned phenomenon. But sinc most people tend to regard their particula problems as unique and 'inside' themselves, som of these will be mentioned here, whilst in Part I other problems will be discussed and it wi become evident that, in fact, *all personal problem are also social problems.*

The childhood years are the formative years an what we later become can only be discussed i their light; furthermore, the child only experiences society indirectly through the medium of th family and, initially at least, is the only tru individualist until moulded into the image o society. What we have so far been discussing ar the basic principles of dynamic psychology without which none of the rest of this section could b understood. Whilst the problems of the chil are to some extent peculiar to the particula family even when it acts under social pressure those of the other age groups result from interaction at first hand with society. The difficultie of the other age groups are not *related* to society but in large measure *created* by society. S whilst adolescence, young married life or bachelorhood, and old age have their problems, the cannot usefully be discussed outside their soci context and properly belong to Part II. Ho true this is will be shown in what follows.

THE CHILD.

A child is described as an *infant* from one mont until he is able to walk at fifteen or sixteen month a *toddler* from fifteen months to the age of 2½, *preschool* child from 2½ years to 5 or 6 years, and *child in middle years* from 6 to about 12 year About the latter period he has, with fairly wid variation, reached *physical* maturity, but it not until the end of adolescence that he ha reached *social* maturity. He can follow a movin object with his eyes at about 4 weeks, contr his head about 16, grasp and manipulate objec at about 28, crawl and sit about 40, and stand an move around at 52 weeks or slightly later. Bu it is important for parents to recognise that a though all children grow up in the same way, the so at different rates. You cannot *teach* a child valk; it will do so when it is ready, *i.e.*, when as reached that stage of controlled movement.

ental Behaviour and its Effects on the Personality of the Child.

omething has already been said about the way which the personality develops and there is d evidence that important traits have arisen g before the child is able to speak or understand ech; whether he tends to be tolerant of himself . others is probably determined in the first six nths of life. Then, and even after acquiring ech, he responds more to what the parent is n to what she (because at that time it is the ther who is the important person) deliberately s to inculcate. For example, a nervous and se mother or one who secretly dislikes the cess of breast-feeding cannot help but convey se impressions to the child through body sions and the adequacy or otherwise of the flow nilk. The two problems facing the infant at breast are, first, that it is unable to foresee the ure and so it takes some time before it comes to n that its hunger and thirst will sooner or later reliably appeased; second, that its emotions of the all-or-none type which it is not yet able leal with and therefore even momentary frus- ion of its needs brings about outbursts of ontrollable rage. In short, it alternates veen states of satisfaction and fury, and the er are so frightening that it may *introject* them which case it feels that there is something d' inside itself) or *project* them against the trating breast or mother (in which case it will that mother is 'bad').

Mature Personality.

ll of us employ both of these mechanisms to with infantile aggression and what we later ome is influenced by which one predominated; e is at one extreme the type of person who, n things go wrong, tends to feel 'I am bad' at the other the type who will tend to blame ers. The former will develop the sort of science based upon fear of having disappointed urt something that is loved (*i.e.*, will have anistic attitudes), the latter will have the sort onscience based upon fear of punishment (*i.e.*, will have authoritarian attitudes). As we see in more detail later, both of these extremes undesirable; for it cannot be too often em- sised that the fully mature personality is one se relationships are neither self-denying nor ying the rights of others but one *based on ual acceptance and respect.* The man or woman denies his or her own rights as an individual becomes dedicated to 'helping' others ely in order to assuage personal guilt-feelings ist as abnormal as the one who projects his l' emotions into the outer world; neither is ivated by anything better than a neurotic mpt to solve personal tensions. Genuinely ful people are motivated by that overflow of for humanity which can only arise from love respect for themselves and that, as we have , comes from the experience of deep and satis- g parental affection in childhood.

Neurotic Personality.

ne effects upon the personality of over-strict el control have already been mentioned and sort of parental behaviour leads to the ssional type of basic personality structure yn in some of the peoples of northern Europe re the approved attitudes are seriousness, hard k, punctuality, acquisitiveness, authoritarian- nissiveness (*i.e.*, a heirarchy in which one does mind being kicked so long as there is an in- r who can be kicked in return), and repressed ession manifesting itself in a superficial mentality or the search for a scapegoat. rich Himmler, whilst responsible for the der of six million Jews, was also a leader in ociety for prevention of cruelty to animals in nany. In southern Europe, on the other l, where parents are more lenient in this ect, the general attitude is easy-going, lsive, warm, and not over-concerned about assage of time. It is true that many Latins are indifferent to animals, but they have no need (as in some other countries) for a society for the prevention of cruelty to children. It should hardly be necessary to repeat that nobody asserts (*a*) that all people who are kind to animals are necessarily motivated by a 'gentleness' which is merely a cover-up for concealed sadism, since many of them are just naturally gentle people to man and beast alike; nor (*b*) is it asserted that there is necessarily an inverse relationship between the degree of affection shown to animals and that shown to people. Obviously the ideal is to be kind to both. But nobody who uses his eyes can fail to see that some people love animals to the exclusion of human beings and that many gentlewomen who are good to their cats are very vocal in informing us that they would "beat a man to death" for whipping a horse, and regular in their attendance at conferences where motions are proposed for bringing back the birch and reimposing capital punishment. Of course, they are perfectly entitled to these views; but they are certainly not entitled to regard themselves as kind and loving or opposed to aggression. Such people are merely displacing the affection normally felt for their fellow men on to animals as a substitute object, or displacing their aggression from its true cause in their personal frustrations towards other substitute objects which happen to be the socially accepted scapegoats of society.

Sexual Development.

Just as 'aggression' has a general application signifying life-energy or drive and the narrower and more common application meaning hatred or anger, so the word 'sex' has a general and a particular meaning. The former is more or less synonymous with 'desire' and this type of sexuality is present from birth, manifesting itself first in the pleasure of sucking where the source of pleasure is the mouth, later in the interest in bowel motions which children experience during the 'house-training' period, and subsequently in the more overtly sexual feelings of the young boy towards his mother and the young girl towards her father at the Œdipus stage. At this stage, about the age of five or six years, the child becomes interested in its sexual organs—though even quite young babies often show a similar interest. All these stages of immature sexuality are described as 'autoerotic' because the main object of love is the self and other people are seen in terms of the degree to which they satisfy or frustrate the child's self-love. Masturbation is natural at this time and later attitudes to sex will be strongly influenced by parental attitudes of permissiveness or severe prohibition since the latter may cause the individual throughout life to feel that sex is something 'dirty' and 'sinful'—a belief which has ruined many a married life. The question of masturbation in later life will be dealt with when adolescence is discussed.

With the passing of the Œdipus stage, the adult conscience begins to develop on the foundations already laid in the early months of life and the parents' values are internalised as the 'still small voice'. However, it must not be thought that this is the whole of conscience because it is still primitive and in later life continues to develop with the formation of an 'ego-ideal' when we consciously try to imitate the behaviour of those we admire and respect. With puberty the sexual drive becomes directed towards the other sex and the child is physically mature, but this level is preceded by a homosexual phase in which the object of love belongs to the same sex. This does not mean that overt homosexual behaviour necessarily occurs, though it is not infrequent, and according to the Kinsey report, the majority of American males reported such experiences, but in this country its most obvious manifestation is the 'crushes' felt by schoolgirls towards attractive teachers or senior girls and the similar behaviour among boys when they admire other schoolboy friends and think girls silly. However, what actually happens depends upon social factors; homosexuality is common in public schools whether overtly or in a more sublimated form, and much less frequent among those who have been lucky enough to be reared in a more natural environment where extreme segregation of the sexes does not occur.

Thus the course of sexual development is a gradually moving away from self-love (autoerotic), by way of love of someone of the same sex (homosexual), towards the wholly other (heterosexual). But since nobody completely leaves behind all the manifestations of the various stages through which he has passed, everyone has homosexual and autoerotic elements in his or her personality.

The Subjective Life of the Child: Fantasies.

No child can avoid the various conflicting situations which are part of the process of growing up from infancy to puberty and after; for, to take the more superficial difficulties first, every child must feel small and helpless in the great world of adults, feel jealous of older brothers or sisters, and even more so of the new baby who intrudes upon his supremacy in his parents' attention, just as the new baby will later feel a particular need to clamour for attention in face of the existing competition.

Now these are some of the situations that are dramatised in fairy-tales and the ancient myths (which have been described as the "dreams of a people"), and form part of much great literature and art. Whilst an obvious function of art is its aesthetic aspect when the artist creates something of beauty, it has another function which Aristotle describes as 'catharsis' (*see also* I6)—that is, by moving people to pity, love, or terror, it helps them to discharge emotional tensions and even to resolve their conflicts by enabling them to see that their individual problem is part of the whole human situation, and by pointing out reassuring solutions. Thus art is a form of psychotherapy and, of course, is often deliberately used to that end in the treatment of mental illness. Keeping at the superficial level, it is easy to see that two very pervasive and readily interpreted themes in fairy-tales are the giant-killer theme which reassures the child that the frequently awe-inspiring 'giants' of the adult world are capable of being dealt with and have their weaknesses, and the theme which pictures the youngest son as the 'hero' who accomplishes all the tasks the older brothers have failed in and wins the hand of the fairy princess. But at a much deeper level there lies a darker and more sinister set of fantasies shared by all of us in a world peopled by demons, witches with iron teeth who devour children, the wicked stepmother who wishes to poison her lovely stepdaughter, all of which are depicted in such tales as 'Hansel and Gretel', 'Snow-white', 'Rumplestiltskin', and the rest. The great Greek plays centre around such incredible plots as that of King Œdipus who kills his father and marries his mother, or Princess Electra who connives at the death of her mother who had murdered her father Agamemnon (*see* H24), and the myths of all countries tell of infants born out of the mouth or navel, of castration, incest, and milder stories such as that of the unknown child reared by simple folk who turns out to be of royal blood.

These horror-comic themes, in short, are universal not because some eccentric invented them but *because we have all experienced them in real life.* The child unsatisfied at the breast has fantasies of devouring the breast and, when these are projected, they reappear as the mother who wishes to devour the child; the mother in one stage of infancy is divided into the good satisfying mother and the bad devouring one, the former becoming the 'fairy godmother' and the latter the witch or evil 'stepmother'. Shakespeare's *Hamlet*, incidentally, is a good example of this mechanism because Hamlet was actually jealous of his late father's possession of his mother but, being unable to accept that the father he also loved could be hated, the wicked uncle-stepfather is made to bear the hated side; psychologically speaking, the bad stepfather and the good murdered father are different aspects of the same person and Hamlet has projected his own incestuous desires for his mother upon the stepfather. Many children quite consciously have the feeling that their mother is not their true parent and that they have more exalted origins. This necessity to think in terms of a good parent and a bad one is later replaced by the realisation that there is simply one individual who is sometimes lovable and sometimes hateful and this ambivalence, *i.e.*, having mixed feelings for the same person, is a step towards maturity, though later it will be replaced by a more discriminating picture of goodness and badness based, not on how people react to us in satisfying or unsatisfying terms, but on more objective standards.

There are two main conclusions to be drawn from this analysis of the fantasies of the child:

> (1) that children are far from 'innocent' in the Victorian sense and have experienced far greater horrors in their own minds than can be introduced from outside. They enjoy, for example, Grimm's fairy-tales because *in an atmosphere of security* at the mother's knee or by the nursery fireside, their conflicts are objectified and the story has a satisfying ending which helps to resolve them.
>
> (2) that the normal child is the ambivalent child who has received enough sense of security from its parents to be able to express openly its alternate affection and resentment which, beginning at an early age, becomes increasingly evident as it grows older when a conflict arises between the need for dependency and its ever-increasing need for independence and self-realisation. Large-scale studies have shown beyond shadow of doubt that ambivalence is characteristic of the normal child; obedience, dependence, and unnatural 'goodness' or compliance are characteristic of the neurotic child; and complete lack of feeling is typical of the potential delinquent.

Intelligence Tests.

All that will be considered at this point is the general validity of intelligence tests and the factors which may influence their results.

Intelligence is simply defined as that which intelligence tests test and, by and large, such tests are correlated with school success—though it would be more accurate to say that these correlations are sufficiently high to be useful but not so high as to exclude other factors in which the personality is involved as predictors to success As one authority puts it, what is tested are those qualities that happen to be useful or regarded as valuable in the industrial society in which we live Recent work seems to suggest that most of those who do well at school are almost certain to do wel (other things being equal) in fairly pedestrian and conventional jobs in which hard work, knowledge intelligence, and not too much imagination are required, whereas genuinely brilliant children with novel ideas may do rather badly simply because though equally intelligent, they are original and rebel against discipline. Intelligence is define (*a*) in terms of mental age or M.A., and (*b*) in term of the intelligence quotient or I.Q. (These term are explained in Section L under **Intelligence.**)

Measurement of Mental Ability.

Since intelligence, like other dimensions o personality, is distributed in a bell-shaped curv with the average people at the top and the ver intelligent or very dull at either end, we can sa that the *normal* category (including 50 per cent o the population) has I.Q.s from 90–110. Thos with an I.Q. of more than 110 are in the uppe fourth of the population. I.Q.s from 110–12 place the individual in a *superior* category, 120- 130 in the very superior category, and from 130- 140 in that of the *near-geniuses.* Geniuses (in th technical, not the popular, sense of the word) ar those with I.Q.s of over 140 and include less tha 1 per cent of the population. At the other end o the scale are the *dull normals* (80–90), the *border line mentally deficient* (70–80) and the *mentall deficient* (70 and below). The latter group in cludes the dull and backward or *morons* (50–70 *imbeciles* (20–40), and the *idiots* who fall below 20

Mental ability, as measured by intelligence tests reaches its peak between the ages of 14 and 20 an subsequently declines slowly until old age, thoug no great decline appears before 50 and even the it is not marked. However, this slow decline i intelligence is compensated for by greater abilit due to increasing knowledge and experience, s whilst John Stuart Mill was obviously a genius b

e age of three and most scientists who achieve
rthing do so by the age of thirty. Verdi's
atest operas were composed when he was over
nty. Nor is there any necessary correlation
ween greatness and high intelligence: for
ugh such men as Mill, Coleridge, Macaulay,
pe, and Voltaire, according to retrospective
mates, would have had I.Q.s in the region of
170–180 group, those with I.Q.s of 100–110
uld have included John Bunyan, Cervantes,
ther, Rembrandt, William Cobbett, and the
t Dryden. Gifted people include not only the
demically and technically gifted, but the
ative and socially gifted.

uential Factors.

mong the factors known to influence the result
intelligence tests are learning how to do such
s (in other words, this is an ability which to
ne extent can be acquired); better education,
ause it has often been demonstrated that even
ntical twins with the same heredity and there-
e the same basic intelligence can have different
.s, the twin with the better education some-
es having an I.Q. of ten or more points above
other; city children do better than country
ldren with an average I.Q. difference of 6½
nts because the city child is exposed to more
nulation; foster-children sent to poor homes
y show a *loss* of their initial I.Q. of up to 47
nts, whilst foster-children placed in good homes
y gain 20 or more. Although gifted children
ne from all social backgrounds, a middle-class
ural background is a great advantage as it
vides the intellectual stimulation the child
ds to develop its gifts. Psychological factors
also important and those with so-called obses-
al traits of carefulness who are always looking
k to see if their previous answers were correct
penalised in comparison with the confident
d who works fast. As regards sexual differ-
es, and those connected with race, we know
re are no significant differences between the
s in overall intelligence and that men do better
some tests, women on others. One of the
nest I.Q. scores ever recorded was that of a
ro girl in North America.

Ve must remember that although the nature of
's mental reactions may be determined at the
nent of conception, it is his external environ-
t, particularly in infancy and childhood,
ch determines his subsequent development,
tal as well as physical. In many of the areas
ne world where people are suffering from mal-
rition, protein deficiency in the very young
ore and after birth) may have lasting effects
ntelligence. As their mothers are also under-
rished, such children start life with a per-
ent handicap.

lsewhere we have noted the importance of the
l's attitude towards education in relation to
ental attitudes towards the child, and when we
e to discuss industry it will become apparent
many countries remain backward in spite of
nical and other aid because of their emotional
social attitudes to such matters as ambition,
king to the clock, financial incentives, and
l change. Those who have always thought
ociety as essentially static and of life as being
rmined by fate, require to change these
udes before they can bring about their in-
rial revolution. It is not lack of intelligence,
socially-conditioned indifference that causes
problems. Other psychological tests which
sure special aptitudes or the personality will
ealt with in Part III.

ADOLESCENCE.

dolescence is manifestly brought about by
ical changes in the body due to changes in the
nd other glands such as the pituitary and the
nal glands on top of the kidneys. Obvious
ly developments begin to take place: men-
ation, the development of the breasts, and the
asingly rounded contours of the figure in
the breaking of the voice, development of
nuscles, and the production of semen in boys,
her with the growth of the beard in boys and
th of hair under the armpits and in the genital
n in both sexes. But even these manifestly
organic changes are influenced by social factors, both psychological and nutritional, and within the present century the average height of each younger generation has increased and sexual maturity, particularly in girls, begins at an earlier age. Therefore, though these physiological reactions *started* the process, it is very important to avoid ascribing to adolescents in general features which are merely typical of our own and a few other societies. On the other hand, once they have been recognised as non-universal, it is still necessary to consider the characteristics of adolescence in the technologically advanced countries and try to discover their social causes.

The Characteristics of Adolescence in the Technically Advanced Countries.

We can begin by taking two accounts of the traits said to be typical of the adolescent in America, one dating back to G. Stanley Hall in 1908, the other to E. B. Hurlock in 1953. Stanley Hall's list includes (with particular reference to the immediately post-pubertal period): inner absorption and reverie; the birth of imagination, illusions, dreams, etc.; self-criticism, scruples; the over-assertion of individuality; a strong tendency to imitation; the assumption of dramatic poses, roles, affectations; folly, absurdities, freakishness; new speech consciousness; absorption in friendship; intense fluctuations in energy and emotional and intellectual plasticity. Hall likened the manifestations of adolescence to the symptoms of hysteria and insanity, and considered it a period particularly prone to religious conversion and other violent personality changes. Hurlock describes the emotional life of the adolescent as characterised by intensity, lack of control, inconsistency, prevalence of long-drawn-out emotions or moods, and the growth of such sentiments as patriotism, loyalty, and reverence.

Comparison with Other Cultures.

Unfortunately both these catalogues of traits, and particularly that of Hall, show by the very language in which they are expressed the lack of sympathy which, in part, makes the adolescent what he or she is: freakish, given to absurdities, self-conscious about his speech, too individualistic and yet given to self-criticism, lack of control, and the rest. Yet, if some of the features mentioned are dated (*e.g.*, proneness to religious conversion and patriotism are less common than they used to be) and others are obviously more typical of the middle- than the working-class adolescent, as a whole they are recognisably true of our society. That they are far from being true of all, or even many, societies is shown by Margaret Mead's study of Samoa where adolescence brings about no conflict or revolt and no neurotic worries; all children from the earliest age have freely engaged in sexual play and, on the arrival of puberty, the girl engages in a series of affairs with the boys of the community each of which is short-lasting. There are no rules which allow members of certain age-groups definite rights and privileges and in this respect nobody may progress faster than anybody else. So far as sex is concerned, the adults are perfectly well aware of what is going on and make no criticisms nor attempt to interfere in any way.

If one looks behind the lists of traits supposedly typical of the adolescent in our society, it will be found that they can all be compressed into a few fundamental problems or conflicts: there is the quest for identity, the answer to the question, "Who am I?"; the exaggeration of the conflict between dependency and self-sufficiency; and, if frequently the subject of prurient interest on the part of certain adults, the rather less significant sexual problems which do not actually arise at this time, though there is more opportunity to accept or refuse approaches from the other sex, to engage or not to engage in overtly sexual affairs.

No Fixed Rules.

The adolescent in our society is in a confused and precarious position. His childish behaviours are no longer adequate or tolerated and the apparently secure and settled ways of the adult have not yet been learned—in short, he is playing a game with no fixed rules. Now this is not so elsewhere, nor was it always so here; in mediæval society everyone had a fixed role to play according to age, sex, and social status just as in Samoa, and even just prior to the last war few problems of this sort bothered the middle-class child. A girl was a girl until she left school, possibly at the age of eighteen or more; a boy was a boy until he went to university or started in a job. This, indeed, is still the case in less sophisticated societies where a boy becomes a man at a specific age and the occasion is marked by initiation rites following which he *knows* that he is a man with full adult rights. In many European peasant communities one can tell an individual's position from his (or her) dress: the unmarried girl, the widow, the bachelor, the married couple, all have sartorial indications of their state. Today none of this exists in the technically developed countries: according to traditional morality, sexual intercourse is forbidden before marriage (at least to girls) and yet the period between the attainment of sexual maturity and the possibility of marriage increases for those who wish to advance themselves. There are no fixed rules regarding the age at which certain privileges are automatically obtained; for example, one piece of research showed that in a suburb in a large American city the age at which parents permitted their daughters to go out unaccompanied varied from fourteen to twenty. The law decides when children may buy cigarettes, parents make their own widely differing regulations and it is understandable that those who see this behaviour permitted in others of their own age-group will feel deprived and embarrassed if it is forbidden to themselves.

Moral Standards

The period at which an adolescent ceases to be a child and becomes an adult not only varies widely in general but even varies in relation to specific activities; it is possible to be a ' child ' in one field and an ' adult ' in others. Hence the adolescent's search for identity, role-playing, imitation of heroes or pop-singers of his own age, self-searching, and resentment of adults. The latter is increased by the ardent moving away from childhood status towards self-realisation as the individual interprets it, and both lead to adolescent assertion, aggressiveness, and the feeling that he is not ' understood '. Nor is he understood, because technical progress and the changes it has brought about in social patterns make even the young parent useless as a model for youth to follow—there is an ever-increasing gap between the generations who cannot understand that each is literally living in a different world and the old rules of even twenty years ago are not always applicable now. Sexual behaviour is as much a sign of revolt and defiance as of genuine sexuality, and having a sexual affair is often regarded as a status-symbol just as smoking in school was a status-symbol before the war. Modern youth is much more knowledgeable about sex than formerly (though still not sufficiently instructed) and therefore less prone to genuinely sexual conflicts than previous generations. Few indeed worry about masturbation, that object of baseless terror to their parents; for they know that it is largely universal and entirely harmless. Of course, many moralists regard it as wicked as they are perfectly entitled to do, but that it is harmless is a medical *fact* which they are not entitled to query. Indeed, the main cause of excessive masturbation is not overdeveloped sexuality but anxiety brought about by threats of this sort.

Good Morals begin with Right Attitudes to Others.

The trouble about sexual morality is that, though some may believe that there are certain fixed standards which determine what is ' right ' or ' wrong ' in this field—and it is impossible to contradict them because this is not a matter science can usefully discuss—in reality all moral standards have varied widely from one place or time to another. It is clear that the basic revolution brought about by Jesus Christ was a realisation that good morals begin with right *attitudes* to other people and cannot be codified in a fixed set of rules that tell people what they must *not* do, and we have given numerous examples from modern psychology to show that when people do the ' right ' thing for the wrong reason they are not likely to be successful in achieving their goal. Saint Augustine put it even more bluntly when he said: " Love God and do what you like "—or as some might say, " If you genuinely care for other people in their own right you't can go far wrong."

ADULTHOOD AND MATURITY.

Psychological Maturity.

It is evident that society decides when a person shall be regarded as adult and that, on the whole, this bears little relationship to biological maturity—much less to psychological maturity which is achieved by few. Among the qualities which are the signs of psychological maturity one must take into account:

(1) Emotional control, which implies that the truly adult person has to learn to defer immediate gratification of his wishes or expressions of his feelings which must become subject to his total way of life—he will learn that it is not worth while giving way momentarily to a form of behaviour which will only be followed by shame or is likely to ruin all that he has regarded as his highest ideals.

(2) The appropriateness of his emotions—that is to say that, broadly speaking, a mature person's emotional responses are objectively relevant to the actual situation facing him and his expression of feelings shows an awareness of those of others. The problem of achieving emotional maturity is not solved by stamping out or denying emotions, however strong or unpleasant they may be; it is a problem of learning to live with emotions, keeping them within reasonable bounds, and of turning them, whenever possible, to the ends of survival of ourselves and others in this complicated world.

(3) The richness and variety of experience, whereby the all-or-none emotions of the infant become highly differentiated, varying from righteous anger or disgust, to wry amusement and the most subtle æsthetic pleasures. Unfortunately most of us, partly from psychological distortions arising in childhood and partly from lack of stimulation from the environment such as inadequate education, never wholly reach this stage and it is obvious that some of the greatest geniuses, whilst adding to our own capacity for æsthetic pleasures, still remained emotionally childish—not with the *child-like* simplicity of a poet such as Blake, but often with the vicious childishness of the antisemitic Wagner or the woman-obsessed yet woman-terrified Strindberg.

Most people are immature in various ways and must simply try to make the best of things and it is probably true to say that many live lives of quiet desperation. Marriage takes place for the wrong reasons because of modern society's obsession with sex and its failure to see that sex without comradeship, compatibility of temperament, and the appreciation and respect due to a partner who is a human being in his or her own right, is bound to fail. Men marry women sometimes as lovely status-symbols, sometimes as mother-substitutes, and sometimes as someone to boss for the lack of any other means of expressing their power obsessions—yet, strangely enough, marriage survives and perhaps has never been in a stronger position as a social institution. But, again, society determines the form of marriage and the structure of the family and exerts pressures upon it for good or ill that must be considered later. Even when the change of life, which is biologically conditioned, makes its appearance in the course of time how it is experienced is socially influenced. Like adolescence, it may become a period of storm and stress, or, on the other hand, the prelude to a contented retirement with enhanced powers of enjoyment both sexual and æsthetic; its connection with cultural factors is demonstrated even within the bounds of our own country where serious depressive states in middle age are much com-

ioner in the more puritanical north than in the
iore permissive south.

OLD AGE.

iological Factors.

Anyone can see that not only do the signs of old
ge come on at very varying times, being some-
mes relatively early and in other cases hardly
pparent at all even in advanced years, but also
iat, when the signs do come, they assume a form
hich is the same for all peoples and at all places.
his is because old age, like puberty and the change
f life but even more so, is brought about by
asically biological factors. These include glan-
ular changes, though the most obvious results
f senility arise from a deterioration of the sub-
ance of the brain caused either by a primary
egeneration of the cells in the nervous tissues or a
econdary degeneration which produces the same
esult by reducing their blood supply when ageing
rteries become hardened and narrow. The ef-
ects of these changes can be summarised by saying
iat senile deterioration leads in varying degrees
memory changes such that memory for recent
vents is poor whilst that for long past events is
sually retained or even emphasised and dwelt on;
iat the individual tends to become emotionally
nstable and, for example, more easily moved to
ears; and that there may be apparent changes in
ersonality.

ocial Influences.

These changes are more apparent than real, for
hat actually happens is that, with the deteriora-
on of the higher centres of control, features such
s jealousy, greed, or meanness, which have
itherto been kept under control, are released.
other words, the senile person 'becomes him-
elf, only more so'. But even in the presence of
such changes as are clearly due to biological factors, social influences are very much in evidence—for example, in our form of society where old people are often regarded as a problem or a nuisance, it is hardly surprising that they tend to become suspicious, irritable, and self-centred.

Technical change has brought a situation in which, unlike that in the old peasant or agrarian community, old people and schoolchildren, up to quite a later age, are unproductive. Whereas in the changing rural communities of today and even in the old East End of London, the grandparents played an important part in the life of the community, looking after the grandchildren whilst their mother and father were at work, advising their own children about matters in which their long life had given them the experience to guide, and acting as the respected elders of the village or suburban group, they now find themselves unwanted. The younger generation is moved out to satellite towns whilst the old people are left behind, alone and lost in a world they no longer understand. What seemed to be eternal verities have gone, and these are needs that even the best treatment in an old people's home cannot satisfy.

Here is another clear example of a biological problem which is also a personal one and at the same time very much a social one to be solved not by charity and misplaced sympathy but by the understanding that comes from a combination of science and caring which are more closely related than is always realised. As Leonardo da Vinci wrote in his 'Treatise on Painting': "In truth great love springs from great knowledge of the beloved object, and if you know it but little you will be able to love it only a little or not at all." Or in the language of Freud, even the most abstract study of the universe requires that the object of our study should be invested with the love we have projected upon it: when hate is projected hate is what is reflected back and we understand nothing.

II. SOCIETY

1. SOCIETY AND CULTURE.

A society is a more or less permanent group of
eople living together and sharing a common way
life and common attitudes and beliefs. Its
ulture is the name given to this way of life, and
e term *physical culture* refers to objects such as
eapons, bowls, art, and in more complex
cieties, an elaborate technology. The people
ho make a special study of different cultures are
own as social anthropologists and when they
st began to take their work seriously and carry
it field studies by living among the people they
ere studying, it was natural that they should
oose primitive tribes as being the most con-
enient because (at any rate at that time, from
e beginning of the present century to just before
e last war) there were many of these primitive
oups which had lived in comparative isolation
d therefore showed the culture in an almost
adulterated form. The culture had remained
changed for many centuries, and among these
ople the social structure was much more rigid and
sily defined than in the larger and more complex
dustrial societies. Nowadays, however, a
cial anthropologist may study any sort of
lture, for example, a Yorkshire mining com-
unity, or a working-class community such as
agenham, a study which is mentioned in Part III.

sic Personality Structure of a Society.

Enough has already been said to show that there
e great variations among different cultures as to
at people consider 'normal' behaviour and the
fferent roles its members ought to play in rela-
on to the rest. Culture not only imposes general
liefs which are expected to be shared by all
embers of a society (for example, its religion and
ythology, or its economic and political system)
t defines the part men and women must take in
e division of labour or rearing the family to-
ther with accepted methods of doing so, and the
les children must follow in dealing with each
her and their parents or elders. This results in
at has been described as the 'basic personality
ucture' of a society, the blueprint for parents
adopt when bringing up their children.

Studies of Primitive Societies.

A brief glance at some of these various cultural ideals in primitive societies is necessary because they are of great practical interest to psychologists and psychiatrists to whom they have given an entirely different view of the potentialities of 'human nature' and caused the psychiatrist, in particular, to re-think what he means when he talks about 'normality', and even what he means by 'mental disease'. Thus the great majority of psychiatrists up to the late nineteenth century, and a certain number at the present day, have taken the view that mental disease is brain disease but this belief requires considerable modification if one finds that serious depression leading to suicide is totally unknown in some communities, that people in one tribal group show many of the symptoms of what in Europe would be regarded as schizophrenia, that the neurosis known as 'conversion hysteria' is commoner in technically backward parts of the world and, even in Europe, begins to disappear as technology advances. Similarly, those who have always supposed that certain behaviour is typical of women and that women are socially and intellectually inferior to men because of their allegedly innate physical weakness and their peculiar glandular structure, will have to reconsider their belief when they find that in some societies women are the dominant sex.

The Researches of Ruth Benedict and Margaret Mead.

Two American anthropologists, Ruth Benedict and Margaret Mead (who has already been mentoned in relation to her study of adolescence in Samoa), began in the 1930s to study various primitive tribes and the differences in basic personality structure that they discovered were striking. To take a few examples: among neighbouring tribes in New Guinea Mead found the following differences in sexual attitudes. One tribe, the Arapesh, had as its ideal the mild responsive man married to the mild responsive woman; another, the Mundugumor, valued the violent aggressive man and the corresponding aggressive woman—in fact, aggressiveness was so strong a feature of this tribe that literally every man hated and feared every other man and the only possible relationship between two men was one mediated by a woman: a third tribe, the Tshambuli, showed a complete reversal of the sexual attitudes regarded by us as ' normal ' with the husband the mild submissive partner who sat at home dressing himself up and applying cosmetics whilst the wife was impersonal, dominant, and managing, doing most of the work outside the home. Benedict found that the Zuni Indians of New Mexico had such a distaste for aggression or even self-assertion that the polite thing to do was to try to lose at competitive games, and leaders could only be elected by locking up some of the nastier members of the group until they broke down and agreed to act as chiefs; once elected, they were regarded with contempt and, at the least sign of self-assertion, would be hung up by their thumbs until they confessed and promised not to behave in that way again. The Arapesh, too, are so unaggressive that the sign of anyone in a rage shocks them as much as any discussion of sex shocked our Victorian forebears. The Dobu of New Guinea live in such a state of persecutory suspicion that a Western psychiatrist would unhesitatingly diagnose them as paranoiacs just as he might diagnose a typical Balinese as schizophrenic, and whilst the Western industrialist tries to acquire wealth, the Kwakiutl Indians of Puget Sound hold ceremonies at which the men compete to discover who can destroy the greatest amount of money in the shortest possible time.

Many societies, like the Greeks of classical times, have valued homosexuality as being a more spiritual form of love than sexual relations with women who exist only to do domestic work and bear children. In the words of Benedict, we have come to realise that " most of these organisations of personality that seem to us most incontrovertibly abnormal, have been used by different civilisations in the very foundations of their institutional life. Conversely, the most valued traits of our normal individuals have been looked upon in differently organised cultures as abnormal. Normality, in short, within a very wide range, is culturally defined."

Cultural Change.

Two important questions arise from these observations, the first is how these various cultures arose and took the particular form they did, the second is the problem of what makes cultures change. The answer to the first question is fairly simple; it is that each culture is a way of life suited to a particular group with certain historical traditions and adapted to a specific physical environment. It is both unconsciously and deliberately passed on from one generation to the next by specific methods of child rearing. " Systems of child training ", writes Erikson, " represent unconscious attempts at creating out of human raw material that configuration of attitudes which is (or once was) the optimum under the tribe's particular natural conditions and economic-historic necessities."

As will be seen in more detail later, the basic personality structure of Western Europe completely changed about the time of the Renaissance from a state of affairs in which conformity and a static social structure was the ideal to one which valued the most extreme expressions of individualism. personal aggrandisement, acquisitiveness, and social mobility. No living things are so variable as human beings and, though the existence of their innate needs explains why they *initiate* certain actions (*e.g.*, why they want to eat, drink, or obtain sexual satisfaction), it does not in any way explain *how* they do these things, why they sometimes do them when they do not wish to, or do not do them when they do wish to; biology becomes subservient to culture and even the most pressing physical needs may become secondary to social needs. Thus in an American town during the depression of the early 1930s, purchases of food declined markedly whilst petrol sales remained at the normal level—obviously the social prestige associated with running a car was more important to many impoverished citizens than having regular and satisfying meals.

Causes of Technical Backwardness.

Whilst such societies as the primitive tribes w have been discussing have shown little chang over many centuries, the technically advance societies are subject to ever-accelerating socia change and, of course, under the impact of Wester technology, even the primitive communities ar beginning to enter a new state of development. I has often been thought that the backwardness o certain peoples was due to some sort of innat inferiority, but the reasons for their apparen backwardness are quite unrelated to any suc factors. First, the use of this term is, to som degree, a value judgment—for who is to sa whether our society with all its many huma problems is ' superior ' or not to simpler societie where, for example, suicide and war may be in conceivable? Second, two of the reasons fo technical backwardness are quite evident: thu the Eskimos never entered an iron age for the sol reason that they had no iron, and brains are o little avail without the appropriate material conditions to work on: furthermore, until recen times. few of these peoples ever had the stimulu of meeting more complex civilisations. We ourselves lived in a state of comparative backwardness until we were invaded and occupied by th Romans. Third, there may be some truth i Arnold Toynbee's suggestion that cultures nee some environmental stimulus to set them movin on the path to progress, and it is of interest t note that nearly all the great civilisations hav developed in temperate lands where nature wa not so harsh as to prevent any elaborate cultur from arising nor so lavish as to make such attempts unnecessary.

Technological Change.

Primarily, says W. F. Ogburn of Chicago, " th cause of social change is the making of invention mechanical or otherwise, and secondarily, th diffusion of inventions already made." Whils new *discoveries* are by their very nature quit original, *e.g.*, the discovery of how to make bronz (the first alloy known to man) from its constituen metals of copper and tin, was something entirel novel in man's history, new *inventions* are for th most part a combination of old elements—that is they are dependent upon already-known principles. It follows that the more of such element or principles existing in a particular culture th greater will be the number of possible new inventions. So although a simple kind of steam engine was devised by Hero of Alexandria (*f* A.D. 62) nearly two thousand years ago, it was o no practical use because before the steam-engin of the eighteenth century could be produced it wa necessary to know about new ways of treating iro to make it harder, the principle of transmittin power from shaft to shaft and from one directio to another which involves knowledge of the toothe wheel or gear, the idea of vehicles travelling o rails, and many other elements. Today, even complicated piece of machinery such as th electronic computer was readily put together b utilising and recombining a large number of elements and principles already known. Technica progress moves at an ever-increasing rate for jus this reason, and as Ogburn has pointed out materia culture grows according to the exponential principle, *i.e.*, like compound interest.

The Social Effects of Technical Change.

Since culture is an attempt to adjust to a particular environment which is now almost entirel of our own making, it follows that the culture o modern society is an attempt to adjust to our man made environment and reflects this material background, and also that, since the pace of development is rapidly increasing, adjustment become ever more difficult. This has been noted alread in the gulf of understanding between generation for even the most modern youth is barely adjustin to the changes of ten years earlier. The situatio is very similar to that described by Karl Mar who whatever one may think of his economi theories, was one of the greatest sociologists wh ever lived. Marx described a substructure o *Unterbau* which he believed to be the economi system of a society, and pointed out that upon thi is built the religious attitudes, ethics, laws, an nstitutions which form the *Oberbau* or supertructure of society. (*See* J27). In fact, the less a body of thought is subject to objective verification, he more is it likely to reflect the substructure of ociety which modern sociologists regard as its echnology. Whilst science is comparatively ulture-free, existing religious attitudes or philosophical systems or ethical beliefs are very trongly influenced in this way; for example, the Reformation (J38) was not brought about by Luther's distaste for the corruption of Rome, ince movements dating back to the thirteenth entury or earlier (the Waldenses (J45), the Albigenses (J2), and that led by Wyclif in England) had felt just the same—it happened *at that time* because Luther's ideas fitted in very well with new individualist attitudes resulting from the arly stirrings of the industrial revolution and German nationalism. Again, slavery would have been abolished in America even if William Lloyd Garrison had never been born and *Uncle Tom's Cabin* had never been written; slavery disappeared because it was becoming useless as a means of production, just as it had previously been supported by moralists so long as it was useful. Reformers need to learn that one can rarely start a rend without pre-existing foundations, frequently accelerate one that already exists, but never reverse trends already moving in a particular direction in response to environmental pressures.

The Stages of Cultural Change.

The development from technical changes to hanges in the ideological superstructure takes place in four stages:

(1) The material invention or discovery.

(2) Changes in the economic and social structure.

(3) Changes in the other parts of the social structure.

(4) Change in cultural attitudes and popular ideology.

Let us take as an example the influence of the steam-engine on woman's position in society. First, the various types of steam-engine led to the evelopment of more efficient and specialised power-driven machinery on the railroads, in the actory, and ultimately in the home; transport is made easier and therefore cities grow larger, industrial work is made lighter, and house-work less onerous. As a result of this the greater physical strength of men becomes less important in many forms of work and women become as fficient as men over a wider field; they are increasingly employed in industry, work becomes separated from home, and gradually there arises an improved standard of living, increased consumption, and a more easy-going attitude to life.

Changes in other parts of the social structure develop more slowly: the modern family is no longer an economic unit as in the agrarian society, and it is losing its rigid social control over its ndividual members whilst, as Folsom puts it, elaborating other functions, most important of which is the more complete satisfaction of the ve-wish, both with regard to marital and parent–child love". There is no longer one single accepted family-pattern, the patriarchal family, but wide variations from the mother-centred family to the egalitarian family and even the filiocentric family, so that power is no longer centred exclusively upon the father and the family is becoming more democratic. Of course, all these developments arose not from any single cause but were helped along by such other technical inventions as gas and subsequently electric lighting the streets and home, the wider knowledge and se of contraceptives, and the mass media which n one of their aspects) led to a wider and faster spreading of knowledge and a levelling in cultural andards.

ultural Lag.

Traditional attitudes and old ways of thinking, however, tend to persist much longer, largely because they are identified with values which are very deep-seated and any attempt to modify these likely to be described as "a lowering of moral andards" or in such terms as "the moral crisis of our time". Of course, there is a moral crisis, but it is due not to change but precisely to the failure to change; it is caused by the 'cultural lag' between old attitudes and a new environment. Thus the so-called 'equality of the sexes' to which all but the least-enlightened pay lip-service is more nominal than real; for what has happened is that, whilst women have gained many new functions, they have lost few of their old ones. The girl who comes back from work at the factory is still expected to do some of the housework whilst her brother is not. There is even an attempt to drag women back to their more 'feminine' role with the appeal of cosmetic, fashion, and home-decoration advertising; papers of good standing intended for both sexes nevertheless have a special section for women as though they were social oddities in a way that men are not; and there is the tremendous number of women's magazines catering for all that is most infantile and written in a kind of baby-talk, stories of how the heroine succeeds in marrying her boss, columns dealing with how to dress, solving one's love-problems, and the rest. As Dr. Viola Klein says, the state of women at the present time is characterised by a dilemma, which is another of the many conflicts inherent in our present cultural situation. "It results from the contrast between a materially changed situation and the simultaneous survival of traditional ideologies and attitudes." One has only to think of the fuss made by many men teachers at any suggestion that women should get equal pay for equal work, to see how true this statement is.

Cultural Change in the Underdeveloped Countries.

In the more technically backward societies, the impact of industrialisation and new mass-production techniques has been even more dramatic. Drucker has shown how "the sweep of mass-production technology is undermining and exploding societies and civilisations which have no resistance to the new forces, no background or habit-pattern of industrial life to cushion the shock. In China the mass-production principle, swept into the hinterland from the coastal cities by the forced migration of industries during the Japanese invasion, is destroying the world's oldest and hitherto its stablest institution: the Chinese family. In India industrialisation has begun to corrode the Hindu caste system: ritual restrictions on proximity and intercourse between castes simply cannot be maintained under factory conditions. In America the Old South, hitherto least touched by industry and still living in the ruins of its antebellum order is speedily being 'tractored off'. Indeed, conversion of the Southern farm into a rural assembly-line seems on the verge of 'solving' the Southern race problem in a manner never dreamed of by either Southern Liberal or Southern Reactionary: by pushing the Negro off the land into the industrial cities."

Whilst we in Britain have had ample time to adjust to the results of the industrial revolution and have not yet succeeded in completely doing so, the danger in these new societies is that what took more than two centuries here is being compressed into a matter of a few years with a consequent risk of serious conflict and the uprooting of old values with nothing to take their place. Unless social scientists work alongside technicians to ensure that social change is smooth, the persistence of traditional attitudes against a new material background may have dangerous results.

Since the end of the last war the introduction of modern medicine to Ceylon has halved the death-rate, largely by virtually wiping out malaria with drugs and DDT; it was reduced from 22 to 11 per thousand in less than ten years—but the birth-rate remains the same and, at the present rate, the population will more than double every 25 years. The failure to make psychological adjustments to situations of this sort has resulted in the great benefits made possible by science in the form of better health, better nutrition and higher standards of living being nullified as quickly as they are being developed.

All over the world man's greed has led, in the words of Julian Huxley, to the despoiling of nature at an appalling rate. "Wildlife is being exterminated; forests are being cut down, mountains gashed by hydroelectric projects, wildernesses plastered with mine shafts and tourist camps, fields and meadows stripped away for roads and airports." Processes such as these are not planned with a view to the greater benefit of people in general but motivated by a blind and stupid acquisitiveness.

2. THE MODERN SOCIETY.

The large-scale modern society differs from the primitive societies, first investigated, in some important respects which will now be discussed.

The Social Structure: Sub-cultures.

The social structure of modern society is much more complex due to the existence of class differences, regional groupings, and different racial and religious or political groups within the national boundaries. These are described as sub-cultures and require to be considered separately against the overall culture of the state. Thus, though all Britons share some attitudes in common which can be described as the national character, a Roman Catholic Briton does not share all the values of a Protestant one; a middle-class Briton has very different attitudes to many things compared with a working-class one; and a Yorkshireman differs culturally from a Welshman. It is necessary to understand this when we are trying to unravel the causes of racial disturbances, industrial unrest, and other problems in which there are two opposed groups failing to communicate because they are simply not talking the same language and see the same events in a totally different light.

We must repeat, too, that national character is not fixed nor is it innate, but like other constellations of traits has social and historical roots. In spite of the complexity of these national groups more or less successful attempts have been made to understand their overall culture: Mead and Gorer have written studies of the American national character, Gorer of the Greater Russians, and Benedict of the Japanese. The usefulness of these studies is shown by the fact that Benedict was able successfully to predict how the Japanese would react to defeat and occupation at the end of the last war. Much of the American national character can be explained in terms of the rejection of the alien father by the children of first-generation immigrants and the fact that most American males are almost entirely reared by women from the possessive mother whose cult has been described as 'momism' to school education which is carried out largely by women teachers. Hence the American suspicion of 'foreigners', their rejection of Europe towards which many have a love–hate relationship, their constant affirmation of manliness and being 'red-blooded Americans' and their terror of homosexuality—the latter attitudes arising from a deep-seated fear of the sometimes overwhelming females who reared them causing a need constantly to affirm their maleness, and the already-noted fact that boys brought up mainly by women often develop latent or overt homosexual tendencies against which they attempt to defend themselves. Jess Stearn's book *The Sixth Man* which asserts that "one out of every six men in America is a homosexual" demonstrates this fear to an almost paranoiac degree and, although almost entirely nonsensical, became a best-seller showing how widespread is this anxiety in the United States.

Rapid Social Change and Social Status.

Another respect in which modern society differs from primitive societies is the rapidity of social change which leads to the discrepancy between old traditions and present realities with results which have already been discussed. In a society of rapid change social status is not only subject to fluctuation as the individual moves up or down a scale created by extreme social mobility, but quite often status is not (as it is in more primitive groups) very clearly defined, and this leads to feelings of insecurity. Since social status is a kind of transference of the child's need for maternal approval towards the need for the approval of society in later life, we can say that the desire for status is one of the most fundamental of human drives and its absence or loss is a common precipitating factor in neurosis.

In the first part of this section we saw how many of the individual's attitudes are derived from the groups to which he belongs, and it is these which are his main source of status, from the small primary, informal groups such as the family, the play-group, the work-group, the group of village elders, the group of housewives who regularly meet for a cup of coffee, to the large and more impersonal secondary institutions which confer formal status, *e.g.*, the army, the professions industry, the churches, and so on. If the primary groups break up, status is in peril.

The Sick Society Concept.

Now, in the view of some authorities, this is just what is happening. The old primary groupings are allegedly disintegrating in what has become a mass society, and the family, the working group, the village council, are being replaced by huge anonymous bodies in relation to which persona status, useful function, and individual significance are lost. It is further claimed that more than any previous society ours is one which persistently stimulates people's desires without being able to satisfy them, and that it is based on conflicting ideals which the individual finds it impossible to reconcile. Whilst accepting the two latter statements with reservations, the present writer, for reasons to be discussed elsewhere, does not wholly accept the first. Nevertheless it is obvious that many supposedly personal conflicts are really imposed upon us by society, and the psychoanalyst Karen Horney believed that the conflicts found in the neuroses are simply a microcosm of socia conflicts. From such considerations as these has arisen the concept of the 'sick society', elaborated on by Halliday in this country and Frank in America, which suggests that since all our mos pressing problems are simply facets of a more fundamental problem lying at the very heart o modern society, they can be dealt with constructively only at the social level. Frank expresses his views as follows: "Instead of thinking of a multiplicity of so-called social problems, each demanding special attention and a differen remedy, we can view all of them as differen symptoms of the same disease. If, for example we would regard crime, mental disorders, family disorganisation, juvenile delinquency, prostitution and sex offenses, and much that now passes as the result of pathological processes (for example gastric ulcer) as evidence not of individual wickedness, incompetence, perversity, or pathology, bu as human reactions to cultural disintegration, forward step would be taken." This is tanta mount to saying—as is quite true—that malari is most suitably dealt with by killing mosquitoe with DDT or typhoid fever by ensuring a pur water supply, but it does not alter the fact that once individual cases have been infected, th physician must have recourse to quinine an penicillin. Certainly we are made what we ar by social pressures, but as individuals we have t learn to live with these pressures and in wha follows an attempt will be made to show tha individual responsibility must still play a part an that we personally can do something to help ourselves.

The sick society concept is both true and usef and, practically speaking, it does three things:

(1) It makes us realise that it is no profitable to try to help people by blamin them and that an additional reason for no doing so is that society (which is anothe name for ourselves) has played some part i making them what they are. One has onl to think of the many moralists who hav supported prostitution in the past because i upheld the 'sanctity' of the family, main tained the 'purity' of the middle-class gir and reduced what might otherwise have resulted in emotional tensions.

(2) It makes us realise that our ow problems, if often peculiar, are never unique

(3) It helps not only in discovering wha these problems are but, by revealing the social background, enables us to see then more constructively, less uncharitably, an points to possible solutions.

If we recall Jung's case of the Quaker who coul not imagine that he had ever done anything wrong et whose son became a thief and his daughter a rostitute, we may see therein a parable showing ow the respectable members of society are not uiltless of creating juvenile delinquency and rostitution because those who engage in these ctivities represent the dark aspects of society nd act as our scapegoats. In a perfectly real ense, we are enabled to remain 'good' because ney are 'bad'.

3. THE FAMILY.

amily Conflicts.

The original family was the extended family of grarian communities which included not only oth pairs of grandparents but also various uncles nd aunts and assorted relatives. It was an conomic unit in which throughout life each ember had a useful part to play; moreover eing large, family tensions were less prolonged if ften no less acute than in the family of today.

The modern family is usually small because hildren, until they go to work, and the old who ave finished working, are economic liabilities, ut this very smallness leads to more intense nd chronic disagreements, the more obvious ources of which have already been mentioned: ealousies between children, parental conflicts, onflicts between parents and children as the latter y to assert their independence, and between randparents, who feel useless and unwanted, nd their children and grandchildren. Other ources of difficulty arising from without the mily are modern society's obsession with com- ercial sex which incessantly stimulates desire hilst conventional morals deny it outlet, and the o less stupid obsession with the achievement of omplete sexual satisfaction as a necessity for a appy marriage. Working mothers in addition to eir other worries are told by reputable psychia- ists that by going out to work they are turning eir children into potential delinquents; many en still refuse to recognise the changing role of omen in society and attempt to reverse the trend y reverting to the 'baby doll' image of woman- ood; the 'housebound housewife' feels the bore- om that only increases with affluence. All these e real problems yet it is undoubtedly true that at o time has the British family been so stable and o mature in its relationships. We hear about the ilures because they are newsworthy and most idely discussed by experts and, as Michael oung and Peter Willmott have shown in their udy of the family in Bethnal Green, all that is ritten about broken marriages, juvenile de- nquency, child neglect, and problem families as "created an impression that working-class milies are disunited, unsocial, and unhappy".

e Present Status of the Family.

We have no space to discuss the fallacies in- olved in this belief, but perhaps this is best done y quoting from two of the most detailed ac- unts of current attitudes towards the family: e study mentioned above on working-class titudes, *Family and Kinship in East London*, d Gorer's more inclusive book, *Exploring Eng- h Character*. Of the modern working-class mily Young and Willmott write: "(Our) im- essions suggest that the old style of working- ass family is fast disappearing . . . in place of e old comes a new kind of companionship be- een man and woman, reflecting the rise in atus of the young wife and children which is one the great transformations of our time. There now a nearer approach to equality between the xes and, though each has a peculiar role, its undaries are no longer so rigidly defined nor is performed without consultation."

In a survey which covered all classes in England, rer discovered that half the married population the country have had no sexual relationships her before or after marriage with anyone else t their spouse, and continues: "What seems me most noteworthy is the high seriousness th which the great majority of English people proach and regard marriage. Whether pre- arital experience is advocated or reprobated, the ect on the future marriage is the preponderating nsideration. Secondly, the high valuation put virginity for both sexes is remarkable and should suspect specifically English." Neither sex pays any appreciable heed to the æsthetic qualities of the other, and when asked to give their opinions on the factors making for happiness in marriage most people mentioned "give and take, understanding, love, mutual trust, equanimity, sexual compatibility, comradeship, a decent income, mutual interests, happy home life, and no money difficulties." One of the biggest surprises in this study was the small number of people who thought that infidelity was a significant cause of marital unhappiness, and most believed that adultery "should not terminate the marriage (if that can possibly be avoided) and does not justify the wronged spouse in adopting violent or aggressive behaviour". This view was accepted by more than half the men and nearly three-quarters of the women. Furthermore, as Gorer says, "there is at least as much tendency to blame oneself for a spouse's dereliction as to blame or punish the offending spouse." He suggests that such attitudes imply a relatively low valuation of 'love' and a very high estimation of the institution of marriage, and concludes: "(I) have I hope illustrated the great importance for English men and women of the institution of marriage and the seriousness with which they consider it. It is marriage itself which is important, not, I think, love or sexual gratification; and marriage is living together, making a home together, making a life together, and raising children. Perhaps even more for Englishmen than for English women, parenthood is the greatest joy and greatest responsibility of adult life."

The Married Couple.

There is therefore ample reason to suppose that most married couples in this country are reasonably satisfied with their own lot even if the new society has also given rise to problems. Here we are going to discuss some of those involved in the husband–wife relationship, and it is convenient to do so under the three headings of personal relationships, sex, and work. But before going into details, it is important to consider what exactly is meant by 'happiness', the goal towards which most people seem to be so fervently striving. Indeed, the word 'striving' sums up very clearly what 'happiness' implies; it is, as one psychologist has said, "the state of going someplace". A person is happy when he or she has certain goals which they are on the way towards achieving, no matter how slowly or with what difficulty. Happiness means movement towards, and the pleasure is in the moving rather than in the achieving—which sometimes comes as rather a disappointment. When the philosopher Schopenhauer said that the lot of man must inevitably be a wretched one because he could only be happy in relation to a previous state of comparative unhappiness, he was perhaps being unduly pessimistic but at the same time he was expressing a profound truth: that there is no absolute happiness, but only happiness *in relation to how we felt before*. Thus a crust to a starving man provides more pleasure than another million pounds to a millionaire.

This was strikingly illustrated in a social survey in the United States where many people of all income-groups were asked by what percentage their annual income would require to be increased in order to make them entirely satisfied. The result showed that *all* income-groups produced practically the same figure; both the fifty-dollar-a-week man and the five-hundred-a-week man agreed that an increase of 25 per cent would be adequate. People talk glibly of the 'essentials of life' or the 'basic essentials', but there is, of course, no such thing; what we already have are the basic essentials for us and we usually want a little more. No amount of affluence can make us happy because happiness is a state of striving for more—it may be more money, more household appliances, more children, more rooms and space or more knowledge and virtue, but it is always more of something. Happiness is quite different from contentment which is a state of not wanting, of being satisfied with what we already have, and it is probable that static communities such as the so-called 'backward' countries or the Europe of the Middle Ages contain more contented people because they can move neither up nor down the social scale nor very easily change their position geographically. Doctors and psychiatrists see plenty of people who 'only' want happiness when what they really mean is that they want peace of mind (which is contentment) or that they want happiness but are not prepared to accept that, since this involves striving, it also means the acceptance of much pain and frustration and hard work. Those who think that happiness is something they are *entitled* to—as the Welfare State or the Affluent Society often leads them to believe—had better think again; the *means* to contentment, yes, the *right* to happiness, no. Men or women who set their aim far above what they are humanly likely to achieve should remember the equation which reads: expectation minus realisation equals neurosis.

Personal Relationships in Marriage.

Now this applies with particular force to marriage; for those who have been dazzled by silly romantic stories or commercial advertising into thinking that they are entering a state of undiluted bliss, and, if that fails, there is always a new washing machine to create happiness by lightening their labour, are living in a fool's paradise. Marriage is a constant struggle throughout life to become more mature, better adjusted to one's partner, more tolerant, but above all it is a constant process of education in human relationships. Maturity has already been defined as a state in which relationships are neither self-denying nor denying the rights of others but based on mutual acceptance and respect, and this is the key to satisfaction in marriage. Nobody is more pathetic and in the end, more distasteful, than the mother who is continually telling her husband or her children or her own mother how she has 'sacrificed herself' for them; for in doing so she is either demonstrating her own insincerity (since what one gives up *willingly* for the sake of others is not a sacrifice any more than it is a sacrifice for a man to give up his game of darts at the local in order to give more attention to his pigeons or the new baby which he finds much more interesting), or revealing her masochism, her stupidity, and, almost always, her malice. What she really wants is to make the others feel dependent on her, to inflate her own ego, show her spite, or cause them to feel guilty. Nobody can usefully help by relinquishing personal rights *unwillingly and unnecessarily* for the supposed rights of others, *because love for humanity begins with genuine self-love and self-respect.* In other words, whilst situations frequently arise in which one must consciously and deliberately give up some personal rights, this is totally different from the case of the mother who keeps on harping about her total self-sacrifice because, as we have seen, her action is not motivated by the desire to be helpful but rather by a neurotic compulsion to feel 'put upon'. Now this kind of behaviour leads to a vicious circle; for the woman's self-induced limitation of her rights as a person naturally makes her increasingly resentful of those who are felt to be responsible for her frustrations and since this resentment must remain unconscious (because it would clash with her self-picture of martyrdom), she can only respond by making herself even more of a martyr in ways which other people will easily recognise to be motivated by malice and spite. She is not only tormenting herself, but everybody else in her family.

The Housebound Housewife.

In order to distinguish between the normal and the neurotic giving up of individual rights, let us take an example from the so-called 'housebound housewife'. Here is a woman who feels lonely and depressed for various reasons discussed elsewhere but, in general, because she has been used to company before marriage and feels isolated when tied to the home looking after young children, or perhaps because she is ambitious and feels that her present position does not give sufficient scope for her abilities. There is nothing surprising or reprehensible about feeling this way in the circumstances, and the normal approach is that she should begin by being fully aware of the total situation and honest about her feelings in relation to it, subsequently doing something practical to alter the actual situation or herself.

Three solutions immediately present themselves:

(1) After discussion with the other members of the family, and having made suitable arrangements for the children, decide that a part- or full-time job is the answer.

(2) To look around for work, studies, interests, or hobbies that can be carried out in the home to alleviate boredom and possibly prepare the path for more interesting work in the future.

(3) To accept the situation and, after careful thought, change her own attitude towards it, arguing, for example, that looking after the home and her young family should be a rewarding and important period of life which will all too soon be over leaving her free to do as she pleases.

At the other extreme is the neurotic solution which occurs with the type of woman who refuses to face the situation constructively and thinks of it in 'moral' terms, denying that she wants to leave the home at all or that the children tie her down and limit her freedom of movement; she is so 'self-sacrificing' that she does not realise that normal love is always ambivalent in which love and anger or hate are parts of the mixture. Her world is composed of black and white, not as in the real world of varying shades of grey. This may lead to the not uncommon type of neurosis which has as its main symptom the fear of leaving the house even for a single moment, because as was seen earlier a conscious fear is often the expression of an unconscious wish. Immediately she puts her foot outside the door or attempts to cross the street, she is suddenly overwhelmed by attacks of sheer panic. What are the consequences of this 'solution'? First, her neurosis prevents her doing what she really wants but refuses to admit to wanting; second, she is punishing herself for her 'wicked' desires but, being frustrated, her unconscious resentment increases and with it her conscious anxiety; third, she is punishing the rest of the family by being 'ill', becoming a professional martyr probably requiring psychiatric treatment, and fills them with guilt both by snide remarks inferring that her condition is caused by overwork, and by coldness towards them, or perhaps by outbursts of irrational and uncontrollable rage. Certainly she is frustrated, but the cause of the frustration lies not in her objective surroundings but in the way she interprets them.

Truth and Honesty.

Normality in personal relationships can be judged by the degree to which one is aware of the objective situation and able to appreciate the nature of unconscious factors motivating behaviour. So far as humanly possible, one is true to one's own nature and truthful in most circumstances. The more mature a married couple are, the more will it be possible for them to be completely truthful with each other but since no one is completely mature, it is not always wise to tell the truth regardless of circumstances because those who do so are not always motivated by a desire for truth but by unconscious motives ranging from the need to purge personal feelings of guilt without the least regard for the feelings of others to the desire to wound. One of the commonest questions appearing in the personal problems columns of women's magazines is whether some sexual peccadillo in the individual's past should be revealed to the husband, to which (unless the act had repercussions which are still having an effect) the simple answer is: certainly not. Assuming that the person is moved to tell because of continuing feelings of guilt or shame then we can only say:

(1) that such feelings, like those of so-called self-sacrifice, are very often a sign of a concealed but overweening conceit demonstrating to the individual's own satisfaction what a tender conscience he (or she) must possess.

(2) that the correct solution to guilt i surely not to permit what cannot be undone to spoil the present—which is a much more practical reason for feeling guilty—but t

resolve to learn from experience and employ it in avoiding similar mistakes in the future;

(3) that if the act must be confessed, then the best person to confess to is someone who is not emotionally involved, such as a priest, physician, psychiatrist or even a sympathetic, reliable and impartial friend;

(4) that the woman (or man) concerned should consider very seriously the *real* motives lying beneath the need to confess, which, as suggested above, are not infrequently the desire to attract attention or even to wound the other partner.

The only circumstances in which these rules ould not always apply are those in which the rong can still be undone or partly undone in hich case the individual's duty is clear, or those which news of the act is likely to reach the ears f the partner sooner or later from some other ource, when it is usually wisest to consider making clean breast of it (though, even then, it would be ise to be sure of one's correct estimation of the bjective situation and the probable response of he other).

nowing Oneself.

The fundamental rules for close personal relationships within or without marriage are: ature affection (which has already been defined), incerity, as much honesty as is wise judged by he criteria above and, most of all, self-knowledge. ne of the ways in which we can become more elf-aware is by observing not merely what we elieve to be our conscious motives, but the consequences of our actions. If a husband or wife esolves to be pleasant and friendly when the ther returns from work yet every time the evening is spent in constant bickering, then there must e some underlying resentment which it would be ore helpful to bring out into the open and discuss rankly, than to continue making futile resolutions hat are never kept. If a particular emotion or ype of event always seems to keep on recurring; or example, if in all our relationships we invariably end up by feeling 'put upon', if we can ever maintain a friendship for long, if a woman ays that her dearest wish is to get married yet he fails to do so, if one allegedly loves a child et is constantly losing one's temper with it, if ther people always seem unfriendly and shop ssistants rude, if we are frequently depressed or nxious without apparent cause, then the causes ust be sought inside ourselves, since it is impossible that the environment is always to blame. he woman who believes that she wants to get arried yet never finds the 'right' man, has ffairs which invariably come to an end, or somehow inevitably seems to fall in love with unsuitable people—married men, confirmed bachelors, or those with latent homosexual tendencies, s obviously not being quite truthful with herself. erhaps she wants to marry but fears the loss of er independence, perhaps she feels incapable of ny close relationship with another, or perhaps she s afraid of sex and motherhood; for the fact is hat even the plainest woman can get married if he wishes, and whether one falls in love or not epends less on that person's objective qualities han on our own deepest needs. In other words, person who really wants love and marriage an't help falling in love. If we are constantly uarrelling with a loved one, it is because we refuse o admit that in certain respects we also resent im, and it is sensible to recall Dr. Winnicott's ictum that the danger arises, not from aggressiveness in itself, but from the repression of personal ggressiveness in individuals. Or, as the poet lake expressed it:

"I was angry with my friend,
I told my wrath, the wrath did end;
I was angry with my foe,
I told it not, the wrath did grow."

ndeed, as the poem continues, the wrath was ovingly nurtured and increased until it finally nded in murder. Anger and aggression must ften be consciously suppressed in ordinary social ituations in which emotion would be inappropriate, but in personal relationships it should ever be repressed but admitted and talked out.

Sexual Relationships.

The belief so assiduously spread by specialists during the 1930s that complete sexual satisfaction in both partners is not only necessary but inevitably results in a happy married life turned the truth upside down; for the fact is that, in general, a happy married life based on love and respect is the cause rather than the effect of good sexual relations. Every psychiatrist has seen many cases of marriages in which physical relations were perfect and yet the marriage ended in divorce, and even more in which the sexual life was not wholly satisfactory but the marriage as a whole was.

The causes of sexual difficulties are rarely anatomical but have their origin in unconscious fears, guilt, and sometimes in ignorance. But ignorance is not as common a cause as used to be thought, not because it does not exist, but because a genuinely loving couple will find it easy in the course of time to make adjustments and discover for themselves. The bogey set up by these foolish 'experts' that women who do not always achieve complete satisfaction are in some way abnormal may have some sort of theoretical background, but it has very little relationship to the real state of affairs in which a majority of women may achieve orgasm fairly frequently, only occasionally, or not at all throughout their married life. Men who are always impotent are not very common and need medical or psychiatric help, but for women the state of affairs is quite different. Most men experience sexual desire initially as a physical need like hunger, whilst women for obvious biological reasons experience desire in a much more complex form which cannot be separated from emotional security; for a man sex begins and ends with the act, for a woman it only begins with the act since she has to think of (and normally look forward to) future consequences. Of course, this is not true of all women, and as contraceptive measures become more efficient and women more socially independent, many regard sex in pretty much the same light as men. But women even more than men have been brought up to feel that sex is unpleasant or dirty, and many people of both sexes are afraid to give themselves completely in love (the childhood mechanism: "If I don't give all of myself to others, then they can't hurt me"), so it is hardly surprising that comparatively few lead a completely satisfying sexual life. In any case, mutual adjustment usually takes some time and many men and women may take years to accomplish this. However, with or without complete sexual satisfaction most couples as we have seen lead reasonably happy lives together because their goal is not sex alone but the maintenance of a marriage and a home.

There are some cases in which this is not so and the help of a psychiatrist or Marriage Guidance Council is required: if intercourse is completely impossible, if one of the partners finds it totally repulsive, if the couple desire to have children and fail to do so, or if, as sometimes happens in women, the act by arousing desires which they are ashamed of leads not only to non-completion but to anxiety and emotional tension. When this happens, the wife may find that following intercourse her nervous tension brings about irritability and this in turn may lead to constant bickering that may threaten to wreck the marriage. All these cases require skilled advice though, of course, they are no ground for worry on physical grounds alone nor are they anything to feel ashamed about. Everybody fails from time to time in some aspect of their lives and, if it cannot be dealt with by ordinary means, the sensible thing to do is to seek expert advice; there is no more need to feel embarrassed about seeking help from a psychiatrist in these circumstances than in seeking help from a lawyer or house-surveyor in others.

The Goal of Self-Realisation.

Gordon Allport, a leading American psychologist, has emphasised that every living being is trying to complete his own nature—in the terms already used here, he is striving towards self-realisation. But his search, depending upon parental attitudes, may take one of two roads.

One road seeks safety through exclusion, through a restrictive and rejective equilibrium employing the mechanism of repression and denial, yet, because the more we repress the more we must continue to repress, the personality inevitably becomes impoverished and incapable of free self-expression. The person clings to a narrow island, restricts his circle, sharply selects what reassures him and rejects what seems to threaten him. The other road is one of relaxation, self-trust, and therefore trust of others. "There is no need to exclude strangers from one's gathering. Self-love is compatible with love of others. This tolerant orientation is possible because security has been experienced in the realistic handling of inner conflicts and social transactions. Unlike the authoritarian and prejudiced person, the tolerant person does not perceive the world as a jungle where men are basically evil and dangerous."

Teaching Morals.

The disasters arising from a restrictive upbringing have to do with the child's early failure to live with his own impulses; he is made to feel guilty and punished whenever he soils himself or is found handling his own genitals. (Incidentally, research has demonstrated that mothers of prejudiced children are mostly likely to punish the child for this offence.) He is punished or made to feel guilty too—and only a child can tell what guilt and pain can be aroused by the hurt and suffering expression on a mother's face which is much worse than a physical blow—whenever he has a tantrum or strikes a parent or other relative. A child who finds his every impulse, even his desire to self-expression, wicked, and feels that he is unloved when he gives way to it—is likely to grow up hating himself for his many transgressions. Says Allport: "He carries a burden of infantile guilt. As a consequence, when he sees any lapses from the conventional code in others he grows anxious. He wishes to punish the transgressor, just as he himself was punished. He develops a dread of the very impulses that trouble him. When a person grows overconcerned with sin in others, the tendency may be viewed as a 'reaction formation'. Having had to fight unholy impulses in himself, he cannot be permissive and lenient toward others. (This) moralism is only surface compliance; it does not solve the conflicts within. It is tense, compulsive, projective. True morality is more relaxed, integral, and congruent with the life pattern as a whole."

The Development of Normality and True Morality.

The way to avoid these developments is obvious. In addition to the fundamental parental attitudes already mentioned, the basic rule is *never to apply prohibitions to a child until it is capable of carrying them out and understanding them.* For example, the senseless attempt to 'train' a child in potting habits before the muscle controlling bowel movements has even been developed is something which is carried out to suit the parents' convenience rather than for the child's own benefit as, alas, in many cases are the sleeping habits and regular feeding habits imposed upon the infant. What parents should realise is that to a considerable extent normality and genuine moral attitudes are developed by a process of internal maturation rather than by any sort of direct intervention on the part of the father or mother whose real job in the early years is to provide the right emotional background. The child who is fed 'on demand', that is, whenever it wants, does not become an anarchist but in a few weeks develops as regular a rhythm as the unfortunate who has regular feeding imposed upon it; the child who is left alone so far as bowel-training is concerned learns control by itself in the course of time.

Young children naturally play with their genitals which, after all, are an interesting part of the body and, quite apart from sex, an obvious object for attention; they should be left alone to do so unless the parents prefer that the child should learn to do the same thing in secret or, worse still, that it should learn that sex is dirty and sinful and therefore to be repressed. In fact the young child's genital play is not initially sexual at all but merely natural curiosity, and it is only the guilt-ridden adult who interprets it in this way.

The Good Parent.

A permissive attitude on the part of parents i the only sensible one because it is impossible t destroy a desire but only to drive it undergroun when it will reappear in far less desirable forms Aggression, even more than sex, is dangerous if no permitted free expression in the early years; th child with a temper-tantrum should be hugge and reassured because it is frightened by its in ability to control this terrifying emotion. Training, until the child has acquired the ability t understand what he is told, is a matter of livin and leaving well alone. (Obviously, this does no apply to situations where the child is in physica danger of falling or touching dangerous objects but even then the minor accident should b minimised as far as possible because the mothe who shows her excessive anxiety infects her chil with it and causes it to feel that the world is dangerous place. It is, but one can handle i better when unafraid.) Thus the good paren must strike a useful balance between sincere lov and concern for the child and the avoidance o inducing too much anxiety by undue fussing abou risks and illness. So far as dangerous situation are concerned, the sensible thing to do is to remov or guard against any potential source of dange rather than worry the child about it.

Sex Education.

Sex education has often been conceived as process whereby the child—hitherto assumed t be totally ignorant of sex—is, at a certain ag (usually puberty), taken aside and given a seriou talk either by the parent, or (as some seem to suppose) by the biology teacher at school whose duty it is naively believed to be. This, of course, i simply nonsense. Sex education begins at birt by supplying the child's physical needs, its psychological need for love, and otherwise leaving it alon to explore its body as it pleases. Later, when i acquires speech, the child who trusts its parent and has not been made to feel that there is anything 'bad' about its natural processes, will star to ask questions. The rules which should b followed by the parents at this stage are clear:

(1) Every question should be answere *honestly* in a way the child at that age ca comprehend;

(2) The answer should be a simple and *brie* reply to what has actually been asked;

(3) Formal sex education, in the sense of more detailed and scientific account, belong only to the later years of childhood when th parents should continue to answer all questions honestly and in the greater detail th child now requires, discussing the *social* implications of sex insofar as they are capabl of doing so;

(4) Sex will finally become something t be taught by the teacher as part of a cours in general biology.

The reasons for this approach are clear: we hav seen that in the early months it is useless—an worse than useless—to apply prohibitions whic the child is unable to understand. When i acquires speech and subsequently goes to schoo it will inevitably obtain some sort of sexual information anyhow, so the parents' choice is no between some knowledge and none at all but between garbled and often nasty information an that which is decent and honest. In fact, th child whose questions have been answered briefl and truthfully becomes *less* interested in sex excep as one feature of life as a whole than the one wh has been told nothing, to whom the secret and forbidden knowledge becomes both a private obsession and a status symbol.

Everybody has a particular desire to acquir knowledge which he or she knows to exist, bu which has clearly been withheld because it i supposedly 'naughty' and 'dirty'. Thus se education is a continual process, inseparable fro education in general; it is, in fact, merely on aspect of personal relationships and should b taught as such. What the child should learn i that, since no form of sex is harmful *in itself*, th ly practical considerations to be taken into count are whether any given sex act is hurtful either person involved, a breach of their self-pect, or a risk to their future happiness—as, for ample, an unwanted pregnancy. It would be ong therefore to encourage someone to engage any sort of behaviour which their religion ches them to be evil, even if we ourselves lieve it to be harmless or even good.

e-marital Relationships.

There are social reasons already mentioned why e-martial relationships *may* be more frequent, d it seems likely that this trend may continue increase. But we might well wonder whether ose who are so alarmed about it (and no decision to its moral desirability can be made here, since s must be left to the reader) are fully aware of background. It is usually assumed that morals becoming more lax in this respect, whereas a ge part of the truth is that people are simply re frank and at less pains to conceal what y do. Again, the kind of behaviour connned by the moralists is very far from being w: for instance, in the heyday of the Church ring the Middle Ages what was then more kindly scribed as the 'natural' child was not only as ll treated as the child born in wedlock, but the m 'bastard' was applied to many exalted ople as an honourable title. In agricultural ieties—including our own—when children were arded as an important asset, engaged couples iberately sought pregnancy because the man nted to make sure that the woman was fertile fore marriage. Another obvious reason for the parent increase in illegitimacy is that the 'shot-n' marriage is less frequent, and a woman who s become pregnant will not marry her lover if subsequently decides that he is unsuitable; s is surely a tendency in the right direction since good can come of an enforced marriage and, in w of the stigma still attached to illegitimacy, ows that the young take these matters more iously today.

4. SOCIAL PATHOLOGY.

We are now going to glance very briefly at cern aspects of what are regarded as some of the re important problems of our day and, since is only possible to select a few, those chosen juvenile delinquency, neurosis and the stress eases, and what appears to be an increase in edom and discontent.

anging Social Attitudes.

Take first of all the background. There is a mendous technical revolution going on in which re exists a lag between the actual environment which we live and our ability to adjust to it; real enemy, however, is not so much lack of lity as ignorance and superstition. For exple, it is indeed true that malnutrition is a ld-wide problem, but it is necessary to realise t the causes of hunger are just as often political l religious as the result of any lack in foodstuff. Asia, one of the main drawbacks to an adequate t is the caste system of India which prevents tain foods from being eaten and in communities both Asia and Africa, as people earn more ney, they frequently spend it, not on food, but clothes and bicycles. Attitudes require nging at least as much as the agricultural tem; *for all the attitudes which we regard as cial problems are common to every country in ch industrialisation and democratisation are ng place* and the mass media are not the cause merely a single symptom of this total process. bellious youth, for instance, and the search for re possessions and affluence is as much in lence in the Communist countries where the lia have been used not only to indoctrinate but to improve, and they are just as common in the countries where the mass media hardly exist. our own country the working class are doing ctly what the middle class were doing when first got into power, only more obviously so ause of the narrowed time-scale within which social change takes place: gambling, buying rather tasteless objects, building rather ghastly houses and fitting them with equally ghastly furniture, reading bad books (the women's magazines of today are really no worse than the writings of Ethel M. Dell and Ouida) and horror comics (which were invented in the late eighteenth century, and the most famous, *Frankenstein*, was written by the wife of Shelley). Of course, the middle class to a considerable extent are still doing these things—but they dislike the working class having the same freedom. Just as one can well imagine the first time that the well-to-do on the Riviera looked with distaste on the newly affluent grocers and 'tradesmen' who were beginning to flood into 'their' preserve, so today the descendants of the grocers and tradesmen view with the same distaste each favourite resort as it becomes flooded with newly affluent workers.

The Cost of Affluence.

But affluence is a state for which a price has to be paid, particularly by youth. In modern society teenagers for the first time have money to spare, are socially emancipated, reach puberty earlier, and have far greater possibilities for success (and failure) than their forebears ever had. A society based on the concept of social mobility, whether the goal is wealth, affluence, or status, must necessarily be associated with striving and the more sensitive members will feel more strongly than others the pressure to achieve, to avoid failure, or even to maintain their present position. In addition, if one has been indoctrinated with the belief that success is essential to self-respect and that affluence is 'normal', it is not surprising that the failures will try to walk round the ladder if they are unable to climb it, *i.e.*, they may attempt the devious way of criminality. Whereas in former times people stole because in some sense they were genuinely deprived, today they do so because they feel relatively deprived. Since happiness is not an absolute, the affluent society aided by the power of commercial advertising ensures a state of affairs in which there is always a gulf between what people have and what they think they are entitled to. Crime and neurosis are the two sides of this single penny; for, as Freud pointed out, whilst the criminal is in open rebellion against his society, the neurotic is in a state of unconscious rebellion. Which 'solution' is selected depends upon a number of factors, one of the most important being social class; for the unsatisfactory upbringing that will tend to make the middle-class boy neurotic will tend to make the working-class boy *living in an area where delinquency is a socially-accepted pattern, or at least not a wholly condemned one*, into a delinquent. Here, of course, we are referring, not to the whole working class, but to specifically delinquent areas.

The Delinquent.

Among the most striking facts about crime are (*a*) that it is predominantly a male, adolescent, and working-class activity; (*b*) that it is at its height in the 14–17 age-group; and (*c*) that, not only do crimes become less violent after the age of 30, but they tend to cease altogether in the majority of cases. An obviously important conclusion of (*c*) is that the majority of delinquents would stop their behaviour regardless of what was done whether by way of punishment or 'treatment'.

It is completely fallacious to suppose that a large majority of criminals of all categories are suffering from some form of mental disturbance, and for the sake of convenience it is useful to consider the following categories: mere wildness and 'proving offences', the disturbed and violent delinquent, the sexual offender, and the professional criminal or old lag. Of course, there are other groups such as those who habitually engage in fraud, blackmail, and shady financial transactions, but these can be fitted into the last of the above categories.

The first type of case is very often a perfectly normal boy who is simply engaged in 'working off steam' and doing the sort of things most of the rest of us have done, since aggressiveness and a certain amount of destructiveness are usual accompaniments of adolescence, or, in the case of the 'proving' offence, he feels the need to demonstrate his toughness or lack of fear by engaging in crimes which are clearly not carried out primarily for personal gain. Typical of these are those who smash street lamps, steal apples or other goods, damage railway property, and so on, or the group of boys who break and enter an office yet, whilst smashing up some of the furniture, steal nothing but a few pencils or other worthless objects. These form the vast majority of all cases and the act, as a German criminologist puts it, is "an episode rather than a symptom", *i.e.*, most of these cases are normal and will develop into perfectly good citizens. More dangerous is the delinquent who takes crime seriously and is often violent towards his victim. Whilst the first group can belong to any class, this group usually comes from a disturbed home and a delinquency area—which is not at all the same thing as saying that he is necessarily abnormal though he may need help: nevertheless, except in grave cases, even this type tends to outgrow his criminal tendencies or, at least, to become less violent after the late twenties. In other instances he may develop into the old lag.

Sexual perversions are, of course, the concern of the psychiatrist and need not be discussed here, but it should be noted that most perverts are suffering from a lack of sexual drive rather than, as popular belief would have it, a state of being 'oversexed'. They are rarely dangerous and most are sexually impotent in normal relationships, but even those who murder with a sexual motive tend to have the same incapacity and a surprising number (*e.g.*, Christie and Haigh) have been brought up in oppressively religious households. The professional criminal is frequently just that, and those who seek complicated psychiatric explanations for his behaviour are usually wasting their time; few people seem to realise that there are those who take to crime as a 'career' just as others become doctors or carpenters. In many instances they are merely 'following the dear old dad'. The old lags or recidivists who form such a large proportion of our prison population are commonly dullards but it is doubtful if many are in the clinical sense mentally ill. As the late Sir Norwood East, one of Britain's leading criminologists, said: "As the result of more than fifty years' practical experience of crime I am unable to regard crime as a disease, although sometimes the result of it."

Crime and Punishment.

Since the great majority of criminals who show early delinquent tendencies simply grow out of them, it is doubtful whether punishment (or for that matter, psychiatric treatment) has any great influence upon the course of events, though detention may often be necessary. But it is really more than doubtful whether punishment has any preventive effect at all. On the contrary, we know that severe corporal punishment can often arouse such a store of resentment as to last through a lifetime of violence and it is also well known that many people commit crimes in order to be found out because they are unconsciously seeking punishment.

How many, one wonders, are aware of the following facts: that the annual average of murders per million of the population in Britain has increased from 3·2 in 1931–40 to 3·3 in 1951–60; that over a fifth of male murderers commit suicide; that between 1955 and 1960 only 31 per cent of offenders were wholly responsible for their actions and that a number of those sentenced to life imprisonment subsequently had to be sent to mental hospitals; that about half the male offenders killed wives, children, or parents, 10 per cent girl friends, and about a quarter strangers (*i.e.* murder is largely a family affair); that, of about 150 murders a year less than a dozen are not cleared up; and that murders with a sexual motive average 8 a year. Murder is therefore very unlike any other form of crime in that its incidence hardly changes from year to year, the number of mentally disturbed cases is large, the vast majority of murders are due to family or intimate quarrels where gain is seldom the motive, and (except for the occasional psychopathic mu derer) the crime is unlikely to be committe again. *See* D34–37.

Stress and Mental Illness.

Before discussing this problem we must sa something about the nature of mental illness, an the first point to note is that, apart from the fac that all cases of mental illness show symptoms disturbance in thought, emotion, or behaviou this is the only factor that they do have common. Without encroaching too far on th material presented by the writer of the Medic Section, mental disorders can be roughly classifie as psychoses (*i.e.*, the insanities), the neurose which are minor if very uncomfortable conditio differing from the psychoses mainly in that th psychotic patient does not realise that he is i whereas the neurotic is all too aware of the fact the psychopathic personalities who are peop that are more of a trouble to society than to them selves; the mental defectives suffering from defect of intelligence; and the psychosomat diseases in which actual physical disease has bee brought about by mental stress.

The causes of these conditions are very variou some like the so-called organic psychoses bein really physical diseases with mental symptom brought about by infections such as syphilis toxins such as alcohol, others such as ment defect being either inherited or caused by dama to the child before birth. The functional ps choses, such as schizophrenia or manic-depressi insanity, have no known physical cause thoug some authorities believe that they have discover abnormal substances in the body fluids of schiz phrenics. But with these exceptions (an possibly a few cases of so-called psychopath personality), we have to realise that '*ment diseases*' *are not in any meaningful sense diseas at all but cases of social maladjustments.* From th fact the following important conclusions can drawn:

(1) that the neuroses and the psychopath conditions—insofar as the latter term h any meaning at all—are really the result of faulty upbringing resulting in a basic defe in interpersonal relations and the sympto are usually brought on by a precipitati cause when the individual is confronted by problem which, by reason of his early expe ences, he is unable to face;

(2) that, unlike ordinary diseases, neurosis is not something that one 'has' b something that one 'is';

(3) that, since nobody has had a complete perfect upbringing, everybody is in so degree neurotic and it is therefore meaningle to suggest that a person is either neurotic not—what we usually mean is that he (she) is neurotic to a degree which troubl him (or her) or troubles others.

The latter is the criterion upon which the pers is declared to be suffering from a neurosis an since this is obviously a matter of individu judgment, it follows that all statistics purporti to tell us the incidence of neurosis in a give community are to a large extent based on val judgments and of very dubious validity.

The figures are made even more absurd by th fact that there must be countless thousan suffering, for example, from a fear of enclos spaces (claustrophobia) who have never seen doctor in their lives and simply solve the problem by travelling by bus and avoiding th underground, and even more who are not awa that they are neurotic at all; they may ha 'nervous indigestion' for which they medica themselves with pills, or believe—as plenty people do—that the state of 'nerves' is a physic one brought on by overwork and curable by 'nerve tonic' or 'nerve food'. These, too, m never see a doctor because they are perfect satisfied with their own medicine. Aga perhaps the sort of neurosis that does most ha is the sort of behaviour described earlier when were discussing harmful influences on childre the possessive and jealous, the mother-in-law w nnot leave well alone, the suspicious wife or sband, those with a profound sense of guilt h which they may infect others. All these are fering from behaviour disorders but few indeed a psychiatrist.

e Structure of a Neurosis.

We must distinguish between the early roots of urosis which are laid in childhood, *e.g.*, the un- isfied need for love and security, resentment ainst authority, and other undesirable patterns behaviour which, being unsatisfied, continue to eat themselves throughout life, and the mediate cause of a breakdown which is the ult of the individual's applying these outdated tterns to new situations. The main difference tween the relatively neurotic and the relatively rmal is that the neurotic tries to apply old utions to new situations whereas the normal rson takes every new situation on its own rits. Thus the man who has had a conflict tween his desire for self-realisation and the thority of a repressive father does not distin- sh between different authorities in later life, ntinues to act on the belief that all authority bad, and naturally frequently finds himself in uble. The man or woman who has felt some nial of love in childhood, continues to seek the nbols of love throughout life in stereotyped ys even if these take many different forms. e individual may become promiscuous, feel timised, become parasitic upon others, overeat, constantly strive for more goods or status. It not that all these forms of self-expression are essarily bad in themselves: what makes them urotic is that they are compulsive. Broadly aking, then, there are two main types of nflict, that which shows itself in the search for proval, love, status, and goods, and the other pe which is a crisis of self-expression, the free- n to assert oneself. The one is shown in the son who looks for affluence, the other in the person who seeks for power, even if both have a common root, the search for security.

Boredom and Anomie.

Many people are bored today because, instead of seeking contentment within, they are in the position of a spoilt child who has been offered so many things that he does not know what to do with them since none is a substitute for love. Whatever point he reaches, there is always something more to desire and each goal as it is reached is less satisfactory than the last. Not only is success less satisfying than it once appeared, there is also the danger of falling from the position achieved, and those who want what they cannot have may become no less neurotic than those who have got what they wanted and are afraid of losing it. It is not only people who want who develop a neurosis but those who have achieved their dreams: the East End family moved to a new town is often troubled by the idea that they will be unable to keep up with the higher standard set by others—there is a 'success' no less than a 'failure' neurosis.

A feature of modern society was described by the French sociologist Durkheim as *anomie*, the feeling of futility and not-belonging as old groups are broken up and the mass becomes the 'lonely crowd'. Social mobility has introduced the working-class student to new ways of life which often arouse a conflict between his attitudes towards his family and the atmosphere of Oxbridge; the worker's new desire to get on often alienates him from his mates; and the housewife stranded at home knows, unlike her predecessors, what she is missing—life is passing her by. There is a gulf between what we want and can have, between what we are and what we want to be; our society is characterised by a never-ending search for the end of the rainbow and for security that will never be ours. The only solution is to learn to live with conflict by seeing our own personal problems as problems to be shared and understood together.

III. WORK

1. THE SATISFACTIONS OF WORK.

Work, no matter how we define it, is not simply nething that we have to do in order to make ney to do something else; it is the main source modern society of status—the sign of approval other people. In the words of an industrial chologist: "Work is the source of man's most ic satisfactions, it is his social catalyst—the veyor *par excellence* of his status and prestige ong his fellows." In former times, status came n one's social position, rank, position in the rch, craftsmanship, or some special ability; few of us today are lords, churchmen, or ftsmen and it is our job that tells others what are. Even from the psychological point of w, it is desirable that our aggressive or creative es should find expression in doing the sort of k that fulfils and helps towards the goal of -realisation. Of course, many people are vely dissatisfied in their work, many more sfied, and others feel that, however well they e done, they might have done better. So it is th discussing, first, what is satisfying about k, and second, the process of education and ction for work.

Work and boredom are not necessarily related, ause from the earliest times work has often been ectively boring but subjectively interesting. the woman washing clothes in the stream, or the man planting rice-shoots, boredom was nown because what they were doing made e to them. The craftsman in mediæval times pride in producing a good and useful article. unfortunate result of the industrial revolution that, while in the long run it created more lth and goods and benefited more people than comparable period in history, it was a first for the majority of workers in the direction aking the meaning out of work. As Christo- r Salmon has said: "Because the Victorians rded work in industry as necessarily hard and greeable, they made little effort to introduce tolerable conditions into mines and mills, and foundries, and were content to think of industry itself as an economic necessity instead of as an element in society."

For work to be agreeable it should be meaningful, and, since most people are sociable to a greater or less degree, the company of one's workmates is important. These are two of the factors which, apart from material rewards, the manager or the industrial psychologist has to consider, and some of the modern views on the subject of incentives will be mentioned later. It will become evident that conditions have much improved in the course of this century, but there is no doubt that they might be very considerably better. The fact that work is not only necessary to man but necessary to most people's mental health as well as being an activity that it is normal to like, stands out in odd contrast to a background of industrial unrest. We shall have to ask ourselves what it is that transforms a necessary and ordinarily pleasant activity into a source of strife.

2. EDUCATION AND SELECTION.

The Past.

In former times education was a privilege of the few and compulsory education was not introduced into this country until as late as 1870. The sort of training given by well-to-do parents to their boys was based on the classics and its intention was to create the cultured gentleman at ease in company and able to discourse intelligently on as many subjects as possible without appearing to be too uncomfortably intelligent. Since science was not regarded as a very cultural pursuit and, until the seventeenth and eighteenth centuries, chemistry and physics were still 'natural philosophy' and hardly existed as sciences in the modern sense, it was little taught at school. Those who practised it were comfortably-off gentlemen who, living more or less in isolation, became interested in it as a hobby. It was only the founding of the Royal Society in 1660 that began to bring these people together to exchange ideas and, since the Society was given a Royal Charter by Charles II, science began to be respectable. Its respectability, however, was conditional and the condition was that it should remain theoretical because gentlemen were not expected to work towards practical ends.

From this attitude there arose the unfortunate distinction between pure science and technology which bedevilled British science and caused parents to feel that technical schools and colleges were somehow inferior to the universities and grammar schools. Of course, another unfortunate result has been that, whereas Britain has never been short of ideas, their serious application has often been carried out in other countries: obvious examples are the jet engine and penicillin. Until much more recently girls, apart from a smattering of languages, music, and drawing, were taught almost entirely such crafts as might be expected to make them good housewives, and the daughters of wealthy parents were not even taught the domestic arts—indeed, since it was believed that any sign of intelligence was likely to put off a prospective suitor, many manuals of instruction suggested that they should actively conceal what intelligence they had.

The Modern Educational Outlook.

Much of this has changed with the acceptance, at least in theory, of the equality of the sexes and the realisation that, as a nation, we cannot afford to waste our human resources. Children are carefully selected at an early age in terms of their abilities and the intelligent child, regardless of his origins, has the opportunity to reach a position consonant with his gifts. But, just as the science-technology dichotomy still persists, whatever governments may say, so other traces of past attitudes make freedom of opportunity less real than might at first appear. Women have not yet gained full equality and we have already seen that what they have gained is more by way of an addition to their traditional tasks than a release from them. One of the greatest barriers to social equality is less any sort of physical barrier confronting the working-class child than the traditional attitudes of his class. It is easy to see why history has made solidarity a traditional working-class virtue and why the boy who tries to better himself is often regarded as a traitor to his class, nor is it unnatural that many workers regard education as synonymous with childhood as work is synonymous with manhood. High culture is still regarded with suspicion as the special province of the ruling class in spite of the fact that, at least since Elizabethan times, most of our great writers and artists have been of comparatively humble origin. These intangible attitudes are obviously a serious barrier to working-class children, as are also the difficulty of finding sufficient privacy to study, the pressures of the affluent society which cause them to want as much money as possible as soon as possible, and the not infrequent family problems centring around the cultural gulf between the university-trained youth and his relatively uneducated parents. Lastly, there is the problem peculiar to England where accent (at least in the south-east) is class rather than regional, and, as Bernard Shaw once said, the child cannot open his mouth without revealing his origins. In a country in which social snobbery is still very real, many can forgive a Scottish, Irish, or Welsh accent, but not a Cockney one. Physical barriers exist, too, because the smaller classes, sometimes the better quality of the teaching, and the limited number of university places in some areas favour the public school child and it is well known that certain universities or colleges prefer the products of particular schools.

Early Specialisation.

The whole concept of education has radically changed, mainly in the direction of very early selection in terms of intelligence and learning ability, and the tendency to early specialisation.
We have moved far from the education of t
cultured gentleman when John Vaizey can wri
that “ it is worth spending money on educati
because it assists the economy, because it provid
a skilled and resilient body of workers at all level
who help to keep a highly fluid economy going
Children are put into various ‘streams’ a
sent to grammar schools, secondary mode
schools, and secondary technical schools. Thoug
the original intention was that there should be
question of any of these schools being superior
inferior to the other the fact remains that paren
are often very upset when their child fails to obta
a grammar-school place and this puts a great de
of tension upon family relationships when bo
parents and children become obsessed with scho
marks and examinations.

The Need for Generalists as well as Specialists.

The situation has arisen out of our need f
experts and many authorities obviously belie
that this is the best way to obtain them. On t
other hand, many others are clearly worried abo
what is happening, the tensions and disappoi
ments and discrimination that it leads to, and a
even beginning to doubt whether excessi
specialisation is a good thing. Like Sir Charl
Snow, they see our nation as coming to be divid
into two cultures—the world of the arts a
humanities and the world of science and techn
ogy. We need the specialists but we ne
‘ generalists ’ too if only because the really creati
ideas—the discoveries rather than the inventio
—have been produced by men who had wid
ranging minds, and though a study of the huma
ties does not guarantee that one will be humane
is rather terrifying to contemplate men specialisi
in germ-warfare or inventing nerve-gases, total
lacking in any knowledge of the men and t
human and natural beauty of the world they a
being employed to destroy.

The 11-Plus.

The doubts of the value of attaching too mu
importance to the results of intelligence tests a
early progress at school are bringing about
movement in favour of abolishing the 11-pl
examination and making more use of the compr
hensive school. London, for example, has decid
to abolish the 11-plus or any sort of single te
which decides whether children should go to gra
mar school or not, and this, in part, is due to t
great success of the comprehensive school. In t
comprehensive schools in the area, the gramm
school, secondary modern, and technical strea
study under the same roof and since these childr
get equal education the need to select at an ea
age is disappearing. Outmoded ideas are rapid
being broken down throughout the country.

Selection Procedures.

Some fortunate people are able to select free
the sort of work they would like to do—writers a
artists, for example—and others simply slide
and out of unskilled jobs, going where the pay
best but the prospects less satisfactory. Toda
however, the vast majority of people, includi
those who are going to fall into the above ca
gories, have to go through at some time or anoth
in their lives various tests to discover their abi
ties. The justification for these tests is (*a*) t
present need for able people with particular qua
fications; (*b*) the need to avoid wastage
attempting to train people who cannot be train
to the necessary level; and (*c*) the obvious fa
that it is a good idea to have a square peg in
square hole and a worker who is not only suited
his job but satisfied with it.

There are three aspects of personality which c
be tested in this way: general intelligence, spec
abilities such as manual dexterity, engineeri
ability, speed of reaction, the absence of colo
blindness, and so on, and tests of personality its
—that is to say, the individual's attitudes.

Intelligence tests have already been discusse
and we have seen that they are by no mea

allible; perhaps their main value is negative her than positive in the sense that, whilst a h IQ does not *guarantee* academic success, we ow that anybody with an IQ lower than about) is unlikely to get far in a university. Aptitude ts are less likely to be met with by the average izen, being mainly employed where a specific requires specific abilities (*i.e.*, in situations ere we know that before the individual is taken o the job he requires a certain minimum of ality x unless time is to be wasted, efficiency ninished, or danger incurred.) Obviously an pilot must be able to react quickly, an engine ver capable of distinguishing between green d red signals, a musician possess a good ear for e, and so on. Most of these tests are very curate and nobody who fails them need feel t down' because they are in his or her own erests as well as those of others.

rsonality Tests.

The personality test is a procedure which, when plied outside its original field of psychiatry, has en rise to a good deal of controversy. One of earliest forms, still used in conjunction with lie-detector employed in criminology, was the rd-association test devised by Jung at the ginning of the century to discover hidden complexes. In this a list of words, some neutral and ers which are believed to have special significance for the patient, is slowly read out and the tee is asked to respond as quickly as possible h the first word that comes into his head. His ction-time is measured with a stop-watch, and delay or hesitation or any unusual responses ed. These give clues to unconscious problems. Today, however, the usual form of personality t is what is known as a projection test, now dely employed in industry as well as in psychiatry discover much more accurately personality its of which the individual is probably totally aware himself—indeed, his unconsciousness of traits is almost a necessity for the use of the t. The three tests of this sort which the reader most likely to come across are the Rorschach or kblot' test, the Szondi test with its photographs of oddly-assorted individuals, and the TAT hematic apperception test in which the outlines vague human figures in various postures in ation to each other are shown. In the first, the tee is asked to say what he imagines himself to e' in the multicoloured inkblot, in the second, is asked to say which of the people in the photograph he would prefer to sit with in a railway riage and which he would most dislike in these cumstances, and in the third he is asked to write tory about the shadowy figures. As the name icates, all three tests are based on the same a—that, presented with a vague situation to ich he has no outward clues, the testee will ject upon the figures or shapes his own attities. When a picture of an apple is presented anyone, he has no choice but to recognise it for at it is, but when he is presented with a rschach inkblot what he 'sees' in it must come n himself. In this way, such traits as introsion or extraversion, authoritarianism or nanitarianism, latent homosexuality, sadosochistic trends, and the degree of integration otherwise of the mind can be fairly reliably essed.

icisms of Personality Tests.

These procedures are widely used in the selec- of management in America and have been erely criticised. The most cogent of these icisms are: (*a*) the moral one that it is an asion of privacy and that no one at a man's ce of work has any right to knowledge of the st intimate type about himself which, if he w, he would not wish to be communicated; the factual one that, although the tests are bably scientific, the uses to which they are put industry are not, since nobody knows what kes a good manager good (in other words, un- aptitude tests in which one knows what one is king for, projection tests reveal material which nly of interest to the psychiatrist); (*c*) the fact t, given knowledge of the technique of the tests, it is very easy to cheat at them. (Those who wish to learn how to do so should consult W. H. Whyte's book *The Organisation Man*.) All that is necessary is to imagine that one is moderate in all things, has no unduly strong feelings either for or against parents and relatives, has conservative views on politics and religion, and has been good—but not too good—at all the tasks one has been presented with throughout life. That, to sum up, one is an insufferable prig and a complete bore.

Group Tests.

Another type of test, or rather group of tests, is that carried out in management selection and at officer selection boards for the army. Here a group of about ten applicants are asked to spend a week-end at a country house (in the case of industry); they are given batteries of tests from intelligence tests to TAT personality tests, are in some cases seen by a psychiatrist who has the test results, and are carefully observed as unobtrusively as possible by trained observers as they interact with each other. The fundamental part of the programme is the group task in which various assignments are given to the group as a whole and, in the course of time, it will be found that, in the discussions as to how these tasks are to be accomplished, those who have superior organising abilities and other useful qualities come to be recognised by the group as its informal leader. Thus in this type of test, it is the group itself which chooses (consciously or unconsciously) the most suitable applicant—not, of course, by votes or words but by behaviour. He is the person who is most frequently turned to for advice during the carrying out of the task, which naturally is related to the activities for which the group is being tested. In the case of industry, for example, it will be the solving of an imaginary business problem, in the army it is usually a problem involving doing things of a para-military nature. All that one can say of this method is that it gives the candidate a better opportunity than the individual interview, since he is checked by a fair number of people and this eliminates the prejudices of selection by one person.

3. THE PROBLEM OF LEADERSHIP IN MODERN SOCIETY.

What has been said above leads us directly to the question of leadership, not necessarily in industry, but in modern society as a whole. We have seen that in many cases there still exists the belief that 'leadership' is a psychological trait which is somehow situated inside a person, being either there or not. Oddly enough, so far as industry and the services are concerned, this innate quality is most frequently found in those who have had a public school education—indeed, one of the mainstays of the argument for retaining public schools is that they train the 'character' and produce qualities of 'leadership' denied to lesser breeds. Scientifically speaking, this is the merest nonsense (*a*) because one can no more train character in a public school than in a borstal or any other place—that has, for better or worse, occurred in the home in the early years of life, and (*b*) because there is no such quality as leadership within a particular man or woman, only the ability possessed by nearly everyone to be a leader in a given situation. Many pieces of psychological research have shown that the only common factor found in those who become leaders in a particular field is their superior competence or knowledge in that area. Of course, many people are thrust into positions of leadership by reason of their social position, their wealth, their education (not what they have *done*, but *where* they have *been*), but these are leaders only in the formal sense and, if many products of our public schools have made good army officers, that is first because they have supreme self-confidence and, second, because they were acting within an authoritarian network in which even the less competent had the full backing of authority behind them. Even the self-assurance is more likely to have been derived from the social background of which their school is only one aspect than from any training within the school itself. This sort of leadership is all very well for the army which of its very nature must be authoritarian, but it is of no use at all in a modern democracy in which a leader must be chosen because he represents the feelings and views of the group he leads. The reason for saying this is not a sentimental one or based on political faith in democracy; it is simply that, in a society which is not authoritarian and where there is more or less full employment, there are no means open to a leader to get his subordinates to work effectively or even to stay with him than by possessing their confidence and respect.

Leadership as a Function of the Working Environment.

We have seen that leadership is a function of the situation confronting the group, so it follows that if the situation changes the leader may have to change too. This is well illustrated in the following case: a factory manager who had been well liked and respected retired and his place was taken by a bumptious, self-assertive man who did not believe in consulting his subordinates. Hitherto, the supervisors had formed their own group which elected one of their members to deal with their interests or problems when he took them to the factory manager for advice, help, or information. Throughout the period of office of the first manager, the supervisors' leader was a quiet, sensible man and the two got on very well together and with the rest of the men. But when it was seen what the new manager was like, resentment began to grow and, at the next election, the old leader was ousted and the man put in his place was an agitator who had up till then been regarded by most of the supervisors as aggressive, unpleasant, and even a little 'cracked'. Year after year the same man continued to be elected in spite of the fact that each member of the group still continued to dislike him, and when they were asked why the answer was: "Well, you see, he's the only man amongst us who is capable of dealing with that (unmentionable) manager."

A Taoist philosopher, about five or six hundred years B.C., made the observation that the great ruler is one whose people do not even notice his existence, the lesser one is feared, and the still lesser one despised. This is confirmed by the leading American authority on management, C. I. Barnard, who wrote that the good leader in industry in a democratic society may sometimes give the impression that he is a "rather stupid fellow, a mere channel of communications, and a filcher of ideas. In a measure this is correct. He has to be stupid enough to listen a great deal, he certainly must arbitrate to maintain order, but he has at times to be a mere centre of communication. If he used only his own ideas he would be somewhat like a one-man orchestra, rather than a good conductor, who is a very high type of leader." Or, as the same Chinese philosopher wrote:

> The best employer of men keeps himself below
> them.
> This is called the virtue of not contending;
> This is called the ability of using men.

In a democracy politics is 'the practice of the possible' because the leader can never be too far ahead of the desires and attitudes of the people.

The Nature of Democratic Society.

A democratic society is, of course, in one of its aspects a society which elects its leaders by secret and universal voting; but this is not the only, or even the most important part of democracy. In modern societies it is often necessary to put people in high positions because of their specialist knowledge—government by amateurs is now no longer possible in all fields, and in industry and other spheres such as the armed forces it is not always possible to elect leaders. What is much more important is (*a*) that the leaders at all levels even when they have been chosen primarily because of their technical qualifications should be able to make themselves acceptable to those under them, and (*b*) that there should be free flow of information both up and down the channels of communication. This is not achieved by manipulating others on the model of Dale Carnegie's book *How to Make Friends and Influence People*— which is often used as a means of influencin people without necessarily making friends of ther —but by being the sort of leader described b Barnard who acts, not on his own decisions take in isolation, but with regard to the feelings o others and an ear to their opinions. There woul be far fewer strikes if management employe genuine joint consultation in which no majo decisions were taken on matters affecting th workers without consulting them about th decisions beforehand, seeking their cooperatio and advice as to how they should be carried out— and this not because of common decency alon but because management *in fact* cannot act with out the cooperation of their employees. Indee many strikes happen not because the worker object to the decisions as such, but because the human dignity is affronted by not being told abou them. Sometimes it is necessary to make d cisions, for example, about redundancy, which o the one hand may be inevitable and on the oth hardly likely to be pleasant to the workers, bu in these cases there is all the more reason why the should be kept informed from the earliest stag and allowed, at least, to express their views as t how the process can be carried out with lea hardship.

An Effective Communication System.

One of the secrets of good management is a effective communication system; for workers w do their job efficiently only when they are able t identify themselves with their firm and feel tha they are taking part in joint enterprise rather tha being used as mere tools. Thus it must be poss ble for all grievances to be dealt with openly a the earliest moment and everybody in a facto ought to know what he is doing, for whom he doing it, and why—the days of 'You're not pa to think: do what you're damn well told,' are, o should be, long past. The widest publicity mu be given to the firm's finances, its future project its exports, and sales within the country becaus as we have seen, nobody works satisfactorily u less he can feel that his work is meaningful. Th real essence of democracy is not any speci technique but the confidence of the ruled that the can influence their rulers, trust them, and recei justice at their hands.

Social Mobility.

Social mobility is another characteristic of democracy, and we have seen that in England t barriers to the right man finding the right job a attaining the highest status of which he is capab are psychological and based on traditions rath than the result of any legal or physical hindranc Indeed, it is surprising to note that social mobili in Britain is freer than in the United States spite of the latter country's tradition of 'from l cabin to White House'. Probably the ma reason for this, as Vance Packard has suggested, that the American manager has little chance success unless he is a WASP (White, Anglo-Saxo Protestant) and, of course, industry is the ma field controlling social mobility and status. Britain the main obstacles for a man are the dyi 'old boy' tradition and the worker's fear leaving his class, but for a woman the sole obsta is simply the fact of being a woman.

4. THE DEVELOPMENT OF INDUSTRIAL PSYCHOLOGY.

We turn now to a brief account of the d coveries in the field of industrial psychology whi had its beginnings in the United States at t turn of the century. One of its first expone was a man known as Frederick Winslow Tay who was to become famous—and, in the eyes some, notorious—as the founder of the syst described as 'Taylorism'. The principles of t system were simple:

(1) to select the best man for the job;

(2) to instruct him in the most effici methods and the most effective movements employ in his job;

(3) to give incentives in the form of higher wages to the best workers.

By applying these principles—which, in a more mane form, were to develop into modern Time l Motion Study—Taylor was able to reduce the mber of workers needed to load wagons at his n, the Bethlehem Steel Company, from 500 to), increase daily earnings of those who remained 60 per cent, and save his bosses about 75,000 lars a year. He was, not unnaturally, un- pular with the workers who, to this day, have vays tended to dislike the man with the stop- tch and if Taylor as a sincere Quaker was basi- ly a humane man and hoped that his system uld benefit all, he nevertheless held the very odd llosophy that "all employees should bear in nd that each shop exists first, last, and all the ne, for the purpose of paying dividends to its ners".

About the same time Frank B. Gilbreth was couraging the fragmentation of work which, as have seen, was already an increasing tendency oughout the middle period of the industrial olution in an attempt to increase efficiency and, be fair, decrease the amount of hard work essary. Like Taylor, his ideal was to make rk so simple that "it could be carried out by a ined chimpanzee". Neither of these two men re trained psychologists, who only entered the d about the time of the First World War and ncerned themselves mainly with experimenting such environmental factors as the influence of nperature, humidity, noise and so on, on effici- ey, but the total effect of all this early work was increase the meaninglessness of the job, arouse entments in many cases, and cause the workers feel that they were being exploited. Since it is essary to most workers to feel that what they doing is meaningful and worthwhile, it is now nerally admitted that if, from the economic nt of view, many of these researches were really cessful, the early investigators took a far too nple and mechanistic view of the nature of the blem. The philosophy lying behind them plied the beliefs (*a*) that man was a machine or, any rate, that his mind could be ignored since real problem lay in adjusting the physical vironment or the way of doing the job; (*b*) that only incentives were 'the carrot or the stick' hat is money or the negative incentive of fear osing one's job; (*c*) that these propositions were f-evident because only a privileged few ever rn to like their work.

e Hawthorne Researches.

These assumptions were to receive a rude shock h the so-called researches carried out in the ly 1930s by Elton Mayo and others at the works the Western Electric Company in the United tes. Mayo was an Australian working at rvard University who initially started off with same assumptions as his predecessors and temporaries—basically, that the main factors improving output were the conditions in the rsical environment of the work-room and, when stern Electric called on him because they were ring labour problems, he proceeded to put them o force. In a work-room where a number of s were assembling telephone relays, Mayo and colleages began by altering the lighting in the m and, after a time, were gratified to find that ductivity went up. Subsequently various er improvements were made in the way of rest- aks, atmospheric conditions, and new wage ns and, following each improvement, the higher put continued to rise steadily. Whilst carry- out these researches, the group of psycholo- s had kept on talking to the workers, asking their views and even for advice, thus arousing eal interest in what was going on. However, good scientist, Mayo did not merely accept others had done before him the satisfactory ults of his work and decided to put them to more rous tests. The environmental 'improve- nts', the breaks, the better wages plans, were oved one by one and, when all had been re- ved and the girls were working in their room n lighting which was of about the intensity of ht moonlight, it was found that production res soared far beyond the highest level ever rded. The conclusions of this piece of work were the now commonplace ones that the rise in productivity and efficiency had nothing whatever to do with environmental changes but were due to social factors such as the girls' attitudes towards each other. Approval, antagonism, or indifference directly affected production, whereas a feeling of importance at being selected for the study, a sense of responsibility and mutual co-operation with the researchers, and growing congeniality among themselves caused a general improvement. In short, it was conclusively proved that human relationships between one worker and another and between all and management motivated them more strongly than financial incentives or good working conditions.

Incentives.

Social surveys carried out by numerous workers in this country and the United States under the influence of Mayo showed that *in all cases money was one of the least powerful incentives*—to take a single example typical of many, the 17,000 employees of Joseph Lucas Ltd. in England put security first and high earnings fourth in a list of seven items which they were asked to place in order of importance. Of course, it has to be remembered that this may change when inflation occurs and prices rise and it may even be the case that, in an affluent society, workers may want more money as an aim in itself, but generally speaking the demand for higher wages is more likely to reflect either dissatisfaction with the firm or a concern with 'differentials'. That is to say, since the workers have their own informal status hierarchy, one group may feel aggrieved if those of a lower status have their wages increased in such a way as to lower the relative prestige of the other—it is the prestige rather than the money that matters, *e.g.*, when the very low wages of the lower grades of railway workers were raised, the engine drivers demanded correspondingly more, not because they begrudged their work-mates their increased affluence, but because their self-esteem had been hurt. The following are some of the relevant facts about incentives in general:

(1) There is no single ideal incentive, because incentives vary greatly from one culture to another (we have seen elsewhere that one of the difficulties in motivating workers in South America and the Afro-Asian countries is their lack of interest in bettering their material conditions), and from one individual to another (*e.g.*, one man may value money whilst another may find more leisure or opportunity for promotion a stronger stimulus to work);

(2) The law of diminishing returns applies to all material incentives, *i.e.*, as the reward increases the desire for further reward decreases until it reaches vanishing-point. Thus the miners, when given higher wages, increased their absenteeism, because the point had been reached at which the need for more money had become secondary to the need for more leisure;

(3) Incentives may conflict with each other; for the worker may ignore financial incentives if he fears that the rate for the job may be cut or that he may work himself out of a job;

(4) It is necessary to realise that in our own culture all motives tend to become 'monetised' since people have subconsciously been taught to believe that money is the key to satisfaction and, when they feel that something is wrong, naturally ask for more money—as Gordon Rattray Taylor has noted "a demand for money undoubtedly indicates that they want *something*, but it does not tell us what".

Restrictive Practices.

We have already seen that incentives can conflict with each other, and one of Mayo's researches demonstrated very clearly the phenomenon of restrictive practices arising from such conflicts. In what was known as the 'bank-wiring room' of the Western Electric Company, he found a group of male workers who completely disregarded all financial incentives and, though the incentive plan provided that the more work a worker did the more money he received, productivity remained at 6,000 units a day in spite of the fact that without the least difficulty the group could have produced 7,000. Here Mayo found that the informal group, which he believed to be the basic unit in industry (it has been described elsewhere as the 'primary group'), had selected an informal leader who was not the same person as the official one. There was an unofficial code of behaviour which exerted a strong influence over group members and impressed upon them the following rules: "You should not turn out too much work, otherwise you will be a 'chiseller'." "You should not tell a supervisor anything to the detriment of a work-mate, otherwise you will be a 'squealer'." "You should not 'act officious'—if you are an inspector, for example, you should not act like one." These are, of course, as Sargant Florence points out, the same sort of principles as are found in the English public school: "Rate-busters have been called 'swots', chisellers, 'slackers', squealers, 'sneaks'. Americans apparently had no name for the form of behaviour described as 'acting officious', but familiar English slang is 'swank'." These form the basis for restrictive practices in industry though here the need to maintain status and avoid the traditional fear of insecurity plays a greater part.

Summary of Mayo's Researches.

Mayo's important conclusions can be summarised as follows:

(1) Work is a social activity in the sense that, even when working in physical isolation as in the case of the artist, what is done is carried out either in society or for society.

(2) The social world of the adult is primarily patterned around work activity.

(3) The need for recognition, security, and sense of belonging is more important in determining workers' morale and productivity than the physical conditions under which the work is carried out.

(4) A complaint is not necessarily an objective recital of facts; it is commonly a *symptom* manifesting disturbance of an individual's status position. Contrary to general belief, the majority of strikes are not about wage claims, but about matters in which the workers feel their status or self-respect to be threatened.

(5) The worker is a person whose attitudes and effectiveness are conditioned by social demands from both inside and outside the work plant.

(6) The change from an established to an adaptive society—*i.e.*, one in which there is great social and geographical mobility, and where a traditionally static society has given way to mass democracy—tends continually to disrupt the social organisation of factories and industry generally.

Two of the dangers of high geographical mobility are (*a*) that a constantly mobile population never has the time to develop loyalty to individual members or individual firms—as one supervisor said, his department was more like a procession than a work-room because its members were continually changing; (*b*) since social control by the superego or conscience is less effective in many fields than control by group-membership, those who never stay in a community long enough are apt to become 'rootless' with a subsequent weakening in moral control. This, of course, is one of the reasons why immigrants are peculiarly liable to get into trouble. It is not their innate wickedness, but the fact that they have left the community which originally supported their moral beliefs, their old cultural imperatives have weakened, and they have not become sufficiently identified with their new surroundings to accept the current mores. Hence the social phenomenon of gangsterism during the 1930s in America was almost exclusively an Italian or Irish one—in fact, even now, the old secret society founded in Sicily and known as the Mafia, virtually rules a large sector of modern gangsterism.

(7) Group collaboration does not occur b
accident; it must be planned for and develope
If group collaboration is achieved, a cohesion ma
result which resists the disrupting effects of th
mass society.

CONCLUSIONS.

What we have found in this brief survey is tha
society is constantly changing in order to adap
itself to a new environment which itself alters wit
disconcerting and ever-accelerating speed.
follows that it is incorrect to say that 'huma
nature' is always the same and that mor
standards never change—on the contrary,
should be evident by now that changes in the
fields are not only inevitable but desirable.
course, there are a few basic laws which a
'absolute' in the sense that they are firmly base
on the nature of society—*e.g.*, "Love thy neig
bour as thyself" is a fundamental rule simp
because society, by definition, is a state of affai
in which most people are neighbourly, and Stua
Chase has said that if more than 10 per cent of an
community failed to cooperate, the communit
would simply collapse.

'Free competition' may well have been in th
interests of society as a whole in a developin
economy, but it is neither possible nor desirab
now—in fact, it was brought to an end some tim
ago, not by the machinations of wicked socialist
but because capitalists could not keep up with th
pace and began to combine to protect their ow
interests.

Again, though we have not presumed to pr
scribe in what direction sexual morality shou
change, there is not the slightest doubt that it
changing and will continue to do so. What
have suggested is that sexual relations must
based on mutual respect and, when that is don
nothing serious is likely to go wrong. This w
the fundamental meaning of the teachings
Christ when he shifted the emphasis from th
externally applied laws of the Ten Comman
ments to inward intentions and motives. Ho
ever, no matter how important sexual moralit
may be, it is very far from being the whole
morality and we might guess that one of th
reasons for the general decline of interest in th
churches has been their tendency to equate s
with sin to the exclusion of the social injustic
which people feel to be among the major issues
our times. If this does not always apply to i
dividual churchmen, it does in general apply
their churches. Very often their influence h
been on the side of reaction as in Spain, and
was an Anglican clergyman who described h
church as "the Tory party at prayer" but, aga
there are many exceptions, such as the attitude
the Church of Scotland to African affairs and th
last Encyclical of Pope John.

In the field of industry what has been said he
may be summarised in the words of Goronwy Ree
"It seems sometimes, today, as if the grand co
mittee of management which has for so long co
ducted the affairs of the country has at last beco
conscious of its failure and seeks desperately for
cure. Hence the 'lofty symbols', the 'admo
tions', the 'signals for a change of heart', whi
we are offered daily. But how are our manage
to cure themselves, and where, in the short ti
that may be left to us, are they to discover eith
the knowledge and competence, or the powers
will, energy, and creativeness, which today
many of them conspicuously lack?" Much t
same might be said of some of the workers' lead
who cannot divest themselves of wholly outdat
notions and superstitions.

We have tried to show that there is a more hop
ful side to the picture presented, notably in t
field of education; but what is clear is that radi
changes in attitudes are needed on all fron
What mainly hinders this is not only the ba
ward-looking traditionalist mentality but, od
enough, the 'affluent society' which, along w
its many benefits, has brought about the state
affairs described by J. K. Galbraith, the emine
economist, and until recently American Ambass
dor to India, when he pointed out that "in
country where well-being is general, the ast
politician will be the one who stalwartly promi
to defend the status quo".

A GUIDE TO MODERN GARDENING

MODERN GARDENING

CULTIVATION OF FLOWERS.

Throughout this section the notes must be taken to refer to cultural conditions in the British Isles, although in many cases the information can be adopted to suit the necessity of readers living abroad. Undoubtedly, in many temperate parts of the world interest in gardening has increased enormously during the past decade or so, despite the fact that numbers of large gardens have ceased to exist and that few people can afford to pay for full-time help in their gardens. To counteract this, the all important labour-saving garden has come into its own; shrubby plants have replaced annual bedding schemes and large lawns put down instead of herbaceous borders or beds of particular plants.

In addition, the owner-gardener is anxious to avail himself of the excellent selection of modern tools; thus the conventional hoe is being replaced by the "Swoe" or the Wolf pattern of Dutch weeder, both of which are very easy to use and digging can be done quickly—and with much less effort—by using a German digger called a "Terrex" spade. For grass mowing, the work is easily done with motor mowers like any of the new battery-driven patterns.

For greenhouse work, smaller houses are being used and one, say, 12 ft. by 8 ft., can be run economically with a minimum winter temperature of 40° Fahrenheit by the introduction of trouble-free, thermostatic heaters or the turbo-heaters. At the moment, besides automatic heating, the prototypes for automatic ventilation and watering are making an appearance.

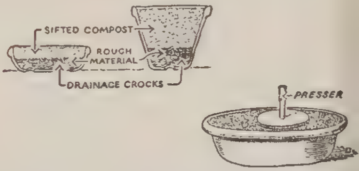
While advocating the use of such appliances, it must be pointed out that there are also to be found tools, sundries, and fertilisers of little value, and many of which have never been properly tested prior to being put on the market. It is, therefore, a good plan to discuss the comparative merits of any appliance or horticultural sundry with a competent horticulturist or to contact a public authority. In particular, many local horticultural societies have special trading facilities, and the merits of most garden things are generally known and discussed among members.

Throughout this Guide the vexed question of change in scientific name has been dealt with as liberally as possible and, whenever necessary, synonyms and cross references are given. In dealing with cultivar names, that is, varietal names like rose 'Peace,' reference is made as recommended in *The International Code of Nomenclature for Cultivated Plants* (1961). By so doing, the references are right up to date and further information on any particular plant or subject is easy to find. For the purpose, a few standard works of reference are given after each section. Normally, all the plants mentioned in the text are available through the usual trade channels.

After each plant listed there is a note on its propagation. Generally, this is the easiest or most efficient way of doing so, but it is not necessarily the only means. Details of the various methods employed are as follows:

Seed. Generally speaking, the early spring is the most suitable time for sowing seeds of trees and shrubs besides those of herbaceous plants and alpines. Where only a few plants are needed, the seed can be sown in pots and a suitable compost made up with 2 parts of soil, 1 part of peat, and 1 part of coarse sand. Before sowing, the pot should be stood up to its rim in water so that the soil is soaked. Then the seed can be sown thinly and covered with a light sprinkling of sifted compost.

For very fine seed, like begonias or azaleas, the seed must have only the merest "sugaring" of sand just sufficient to anchor it. When sown, the pots should be covered with a pane of glass (to prevent evaporation) and kept, possible, in a warm greenhouse or frame. Wit this method of propagation it is important remember that failure will result if the seed sown too deeply, if the temperature is too low, if the soil is too dry.



CORRECT PREPARATION OF SEED POTS AN PANS—Note provision for ample drainage an compost to rim of its container. After sow ing, the containers are covered with a she of glass.

Cuttings. There are two main types of cuttin soft-wood cuttings made from fresh, green shoo in the spring and summer and hard-wood cuttin made of mature or semi-mature woody shoots the autumn. A soft cutting is taken about 3 i long, the lower leaves removed and a clean c made through a node in the stem. These are th inserted in pots containing a light, sandy so or a rooting medium such as horticultural vermiculite, well watered, and covered with a bell j or plastic bag. Delphiniums, hydrangeas, a lupins are all propagated in this way.

Hard-wood cuttings are taken in the autum and made from shoots about 8–12 in. long. The are inserted in a sandy soil out of doors or in cold frame, and left to develop for a year. Blac currants, forsythia, and roses can be propagat by this means.

Layering. This is one of the easiest ways propagating the majority of woody plants, a is used to increase stocks of plants like clemat lilacs, and rhododendrons. Normally, layering done in the autumn or spring when suitab branches are pegged down. On each of these t young shoots are, in turn, pegged down and ti turned upwards and tied in position. To e courage rooting, gritty sand and peat should worked around each layer, and usually the you plant can be severed from the parent after abo eighteen months.

Division. By this method it is easy to pr pagate the majority of herbaceous plants, so rock-garden plants, and a few shrubs. A f herbaceous plants, like delphinium and paeon are slow to get established after moving, a here the method should not be employed. any case, old plants should not be split up in wholesale manner; instead, it is far better select a few young healthy plants, divide the and replant the best of the young shoots, in t autumn.

ALPHABETICAL LIST OF ORNAMENTAL PLANTS.

Abutilon.—The greenhouse species is often us in public parks for bedding schemes. *A. vi folium*, with white, mauve, or blue flowers mak a fine wall shrub for warm gardens. If giv full sun it will quickly reach 10–15 ft., but sometimes short-lived. *Prop.*—Easily rais from seed sown in March in a warm greenhouse frame.

Acer (Maple).—Hardy, ornamental trees; the rway maple is often planted for its magnificent umn colour and as a lawn tree. *A. palmatum* l vars. constitute the Japanese maples; all our brilliantly in the autumn but do not grow ely unless given some shade and a light soil h in humus. *Prop.*—Seed, layering, or budg.

Achillea (Yarrow).—Grey-leaved perennials for n border or, dwarf species, for rock garden. lued as a cut flower, particularly *A. ptarmica* erry's White,' with double, white flowers and *eupatorium* 'Gold Plate,' with large, flat, low flower heads. *A. millefolium* is a perniis weed of turf (T33). *Prop.*—Division in umn.

Acidanthera.—Scented, bulbous plant introced from Abyssinia. It is not difficult to grow he corms are planted in the spring and lifted the autumn for storing in a frost-proof shed. requires a sunny position and plenty of water the summer. *Prop.*—Offsets removed when old crop of bulbs is lifted.

Aconitum (Monkshood).—Blue-flowered perenl plants particularly useful for lightly shaded itions or full sun; flowers from May to July. ght 3–5 ft.; roots poisonous. *Prop.*—Seed or ision.

Adiantum.—*See* Ferns.

A Well-Grown Agapanthus—In winter the pot should be kept in a cold greenhouse or some protected place; in summer afforded full sun.

Agapanthus.—A bulbous plant, native of South rica, usually found in seaside gardens and someles grown in tubs; flowers blue, violet, or white. needs winter protection in the form of a covering bracken or straw and a light soil heavily iched with manure. Worthy of wider cultivan. *Prop.*—Seed or division in March.

Ageratum.—Blue-flowered carpeting plant. Annuals.

Allium (Flowering Onion).—A genus of nearly species of bulbous plants widely distributed er the Northern Hemisphere. The foliage has distinctive smell of garlic, but some species grown for garden ornamentation; in particular *roseum*, valuable late-flowering rock plant for positions. *Prop.*—Offsets, taken from parent bs in the spring.

Alstroemeria aurantiaca (Peruvian Lily).—This erous-rooted, herbaceous plant is often grown cutting. Flowers orange-red and height 2–3 of easy culture if afforded a sunny position left undisturbed. For best results apply uid manure or soot water when growth starts. *op.*—Seed or division.

Althaea (Hollyhock).—A truly delightful, oldrld plant, but not often seen, as modern hybrids have given way to rust disease. Best grown in a rich, heavy loam. Mulch with manure of any sort and stake as necessary. *Prop.*—Seed in June, thin out, and transfer to flowering position in September. Although a perennial, in some localities the best results are obtained by treating it as a biennial and raising a small supply annually.

Alyssum.—Low-growing annuals and perennials for rock garden and sunny border. The perennial, *A. saxatile*, is deservedly popular by reason of its bright, spring flowers and value as a wall plant. The variety 'Citrinum' is bright yellow and 'Dudley Neville' biscuit-yellow. *Prop.*—Perennial sorts by cuttings in June.

Amaryllis belladonna.—Often this plant is confused with the greenhouse, bulbous plant, *Hippeastrum*. The true amaryllis is a half-hardy bulb for planting at the foot of a warm wall; it has white to pinkish-red flowers. When planting, cover neck of bulb with an inch of soil and leave undisturbed, as the plant resents moving and is slow to get established. Lack of flowering is generally due to planting too deep. Established clumps may be fed with hoof and horn meal at 2 oz. per sq. yd. in July. *Prop.*—Divide and replant clumps in early July.

Amelanchier canadensis.—A large shrub or small tree; valuable for its spring flowers and autumn colour. As it will grow almost anywhere in sun or shade, it makes a good plant for informal screening. *Prop.*—Seed or layers.

Amepelopsis.—*See* Parthenocissus.

Anchusa italica.—A blue-flowered perennial with fleshy roots, growing to a height of about 3 ft. Responds to feeding and needs a position in full sun. *Prop.*—Root cuttings in the spring; division in the autumn.

Anemone.—The tuberous-rooted section includes the 'Caen' and 'St. Brigid' strains. These are best grown in an open position in light, rich soil; plant in October, lift and store when foliage dies. The hardy, fibrous-rooted perennials are varieties of *A. hybrida* (syn. *japonica*) and constitute one of the most accommodating of perennials, being particularly useful for damp, shady positions. Worthy of wider attention from gardeners. *Prop.*—Perennial sorts by division in autumn.

Annuals.—These are plants which develop from seed, flower, fruit, and die within a year. Additionally, some perennials, like antirrhinums, may be treated as annuals for the convenience of their cultivation. Sunny borders may be planted solely with annuals, they may be interplanted with perennials, used for window boxes, or, occasionally, in the rock garden. All sorts do best in well-worked, light loam enriched each year with a dressing of fish meal at 3 oz. per sq. yd., ten days before sowing or planting.

In the division of the group Hardy Annuals may be sown in the open ground as soon as conditions permit during March or April where the plants are to flower. Wet or cold soils will give many failures, and fine seed should be covered only with the lightest sugaring of soil. Often surprising—but delightful—results may be obtained by sowing broadcast mixed seed of annuals specially offered by some trade houses.

To raise Half Hardy Annuals, seed may be sown in early March in a warm greenhouse and the seedlings pricked out into boxes. Subsequently, the plants are grown on in a cold frame, gradually hardened off, and then transferred to their flowering positions towards the end of May.

Anthemis tinctoria.—Hardy perennial with feathery, grey foliage and flowers in varying shades of yellow. Height 2–3 ft., needs full sun and good for cutting. *Prop.*—Division in the autumn. *Anthemis nobilis* is the chamomile sometimes unwisely used to make lawns.

Antirrhinum (Snapdragon).—The popular bedding plant requiring a good soil and position in full sun now largely in disfavour owing to rust disease; planting should be restricted to rust-resistant varieties. *See* Annuals.

Aphelandra squarrosa.—An evergreen, perennial plant introduced from Brazil. Often sold as a house plant, albeit a warm temperature and a high humidity are necessary for its cultivation. When grown indoors it is best discarded when the flowers fade and the foliage starts to wither, as it cannot be successfully grown on from year to year under normal conditions indoors.

Aquilegia.—The modern race of hybrids are the result of much interbreeding with wild forms to give a wide range of colours. Best when planted in light shade where soil is naturally moist. *Prop.*—Seed in late spring; transplant to flowering position for following year.

Arabis caucasica.—Once known as *A. albida*, this common rock plant is often used on dry walls. The double-flowered form is particularly good. *Prop.*—Cuttings in July; a fresh stock should be raised regularly as the special forms tend to die out.

Araucaria (Monkey Puzzle).—This tree was introduced from Chile, where it forms large natural forests, and widely planted in Victorian days. Browning of foliage suggests lack of water in the summer or, occasionally, effects of very cold weather. It should be planted in a position protected from the prevailing wind. *Prop.*—Seed in a warm greenhouse.

Armeria maritima.—A hardy perennial with pink or red flowers in the spring; must be grown in full sun where the soil is dry. *Prop.*—Division after flowering.

Artemisia.—A genus of shrubs and perennials suitable for sunny borders or rockeries. *A. lactiflora* is among the best of the herbaceous species, having grey foliage and creamy-white flowers. *A. abrotanum* (lad's love) in the shrubby section has grey, fragrant foliage. *Prop.*—Herbaceous section by division; shrubs by cuttings in the early summer.

Arundinaria.—*See* Bamboo.

Aster (Michaelmas Daisy).—By careful breeding this plant has been improved out of all recognition, and many first-class varieties are available in the trade. Responsive to good cultivation, it is used for its colour late in season and properties as a cut flower, particularly *A. yunnanensis* 'Napsbury' and *A.* 'Barr's Pink.' A wide range of colours are available besides some fine, low-growing forms. In the border one pleasing combination can be made with *A.* 'Harrington's Pink' and *Scabious* 'Dinkie.' *Prop.*—The clumps should be split up *annually* in the spring, and only the plumpest pieces of outer root replanted.

Aster, China or Common.—*See* Callistephus.

Astilbe.—Allied to the *Spiraea* and useful for planting in moist, rich soils; flowers white, pink, and crimson; height 2 ft. *Prop.*—Division of clumps.

Aubrieta.—A name often misspelt. Throughout the country it is used as edging or for dry walls. Many lovely sorts available apart from the commonly found, pale-blue variety. It is a lime lover. *Prop.*—After flowering the plants should be severely trimmed and, as necessary, stock increased by division.

Aucuba japonica.—Much maligned and overplanted shrub, but one tolerant of neglect and sunless or smoky conditions. Interesting variants of the type, like 'Crotonifolia,' may be found in trade lists. *Prop.*—Cuttings rooted in the open in July.

Auricula.—Correctly known botanically as *Primula auricula*. Flowers of alpine auriculas are white or yellow, while in those of florists' auriculas are to be found some of the most delicate colourings among hardy plants Choice varieties are grown in pots under glass; others in moist, shady borders. *Prop.*—Seed or division in th spring.

Azalea.—*See* Rhododendron.

Bamboo.—The common name for the larg group of woody grasses, reference to which i difficult owing to the confusion in their nomenclature. Often grown for screening and wind break and is a favourite shelter for small birds; the bes for home-grown canes are *Phyllostachys virid glaucescens* and *Sinarundinaria nitida*. An interesting account of bamboo growing is found i the *Jour. Roy. Hort. Soc.* (June 1957). Growt can be encouraged by feeding with sulphate c ammonia and mulching with leaf-mould in th spring. *Prop.*—Division of clumps in late spring transplants must be kept watered until established.

Begonia.—A genus showing wide diversity c form and much horticultural value. Of particula interest is the tuberous-rooted section, of whic many of the loveliest varieties have originated i the nurseries of Messrs. Blackmore and Lando at Bath. For bedding schemes, the tubers ar started in boxes of rich soil under glass in lat March and planted out 9 in. apart in June. During the summer feed with liquid manure of an sort and keep moist in dry periods. *Prop.*—Cuttings in early spring in a warm case.

Berberis.—An extensive genus of beautiful an easily grown shrubs, evergeen and deciduous; th former used mainly for beauty of flower, and th latter for autumn colouring and ornamental fruits *B. stenophylla* makes a fine evergreen hedge invaluable for preventing illicit entry by dogs anc even, unruly children. *B. aggregata* and *B jamesiana* are among the best berrying kinds Prune in the winter by removing old wooc *Prop.*—Seed in spring or layering in autumn.

Buddleia.—Deciduous shrubs of easy cultur for sunny positions. Varieties of *B. davidii* available in range of colours from purple to white best when pruned hard by cutting all previou year's growth back to main stems in February The weeping species, *B. alternifolia*, often grow as a standard; good specimens at R.H.S. Garden Wisley. This sort must be pruned in the summe by cutting off the dead flowering stems. *Prop.*—Cuttings in July–August in cold frame.

Cactus.—In the main grown in cool greenhouse or as house plants and, if cultivated well, man will flower every year. As a general guide, plant should be watered fairly freely in the summer an little in the winter, but there are exceptions. detailed account of growing these fascinatin plants will be found in *The Cactus Grower's Guid* by Vera Higgings (Latimer House), 1946.

Calceolaria.—Seed of the greenhouse biennia sown in June or July for flowering in the followin year. Mixed seed provides a wide range of colou *C. integrifolia* is a half-hardy perennial, raised b cuttings or seed, for greenhouse or bedding worl

Calendula (Marigold).—This common hard annual is freely raised from seed sown in Augus Of easy culture in any sort of soil, although it worth getting seed of new varieties now availabl *See* Annuals.

Callistephus.—The China asters are among th best half-hardy annuals for garden and indo decoration, but good soil and full sun are necessar for best results. *See* Annuals.

Camellia japonica.—Hardy, evergreen shru rightly beloved by connoisseurs and cultivated gardens for many centuries. May be grown cold greenhouses, woodland gardens, and again north- and west-facing walls; under all conditio camellias must have a moist, acid soil. Be varieties for outdoors are 'Althaeaflora' (da red), 'Donckelarii' (red, white marbling), ar 'C. M. Wilson' (pink). Of recent introductio is the desirable *C. williamsii* bred from *japonica* in part; often the subject of televisio and gardening notes. The dropping of buds thought due to dryness at the roots at some tin sharp fluctuation in temperature. *Prop.*— ned varieties by cuttings under glass in early y. Otherwise plants easily raised from seeds own in the autumn immediately they are ripe, cidic peat and kept moist.

ampsis grandiflora.—Sometimes found listed as *nonia* or *Tecoma*; choice deciduous climber for m wall, large reddish-orange flowers in umn. To encourage flowering growth, prune d back to old growth in spring. *Prop.*— tings in April struck in a warm case.

anary Creeper.—*See* **Tropaeolum.**

andytuft.—Hardy annual (*q.v.*) and perennials h white, crimson, blue, or purple flowers. The ennial—*Iberis sempervirens*—is a fine plant for ock wall. *Prop.*—Seed or, perennials, from tings.

arnation.—*See* **Dianthus.**

entaurea (Cornflower).—The perennial species valuable for cutting and border use, and may found in such colours as pink, crimson, and ow. *Prop.*—Lift and divide every third or rth year. The hardy annual, *C. cyanus*, is en sold as a cut flower. *See* **Annuals.**

haenomeles speciosa.—This is the correct anical name for japonica. The species commly grown is a wide-spreading, rounded shrub, 0 ft. in height, and often used against walls. s a plant of easy culture with best results being ieved by the annual spurring back of the cur- ; season's growth in the same way as an apple is pruned. All japonicas can be used for king jelly but, for this purpose, the best one is *enomeles cathayensis*, a gaunt shrub about 10 ft. eight which bears fruit up to 8 oz. in weight. obtain a crop within a reasonable time, two or e plants may be set in a group about 5 ft. rt. If growth or flowering is below par all onicas should be fed with "Growmore" and ched with compost.

heiranthus cheiri (Wallflower).—Among the st displays of this biennial are those found each r in the public gardens of Southend-on-Sea, re it is used in conjunction with bulbs and et-me-nots. *Prop.*—Seed sown thinly in rows May and seedlings thinned or lined out and n transplanted in late autumn. The so-called erian wallflower, *Erysimum asperum*, which bright orange flowers, is grown in the same , but it is intolerant of wet soils. Both sorts lime lovers, and on acid soils plants may re- e treatment with 1 oz. of lime in a gallon of er.

himonanthus (Winter Sweet).—Hardy, winter- ering shrub with heavily scented flowers. ough brought to this country from the Far t in the mid-eighteenth century, its garden e is not widely appreciated. The large- ered, yellow sort, *C. praecox*, is particularly , but like all the varieties, it is best grown nst a sunny wall and where the soil tends to be r. If growth is excessive and flowering poor, back young growth severely in March to urage short, spur-like shoots. *Prop.*—Easily ed from seed or layers.

hristmas Rose.—*See* **Helleborus.**

hrysanthemum.—Hardy annual sorts are avail- in a wide range of colours and give a fine lay in the summer months. *See* **Annuals.** re are also a number of perennials such as the ta daisy and the oxeye daisy for sunny, aceous borders; all do well in ordinary soil, should be lifted and split up about every three s. The plant sold by florists in the autumn he Japanese chrysanthemum. Many are ly out-of-doors, but no plant is more respon- to good cultivation and normally is best left he specialist grower. For ordinary garden k, the best sorts are the Korean and Otley s. Under a brief reference the interesting ils of cultivation cannot be dealt with fairly, reference to specialist books is recommended.

Clematis.—A hardy climber for walls, screens, pergolas, and the like. Best kinds are to be found among named varieties in nurserymen's lists. A light, well-drained soil is necessary and if fed annually with a bucketful of manure or compost the plant will thrive for many years. Occasionally plants will be found on north walls, and if grown in full sun some light protection from the sun is desirable for the roots. Varieties which flower on the *current* season's growth, like *C. jackmanii*, should be pruned in late February to within a foot of the ground; other sorts should have sufficient old growth removed, after flowering, to keep them within bounds.

Unfortunately, the climber is sometimes killed by clematis wilt, a disease about which very little is known, and the premature death of young plants should not be blamed automatically on the supplier. *Prop.*—Layering, by which means one shoot will often give three or four plants.

Convallaria majalis (Lily of the Valley).—Well-known perennial that will thrive in any damp, shady position. For best results lift every four or five years and mulch annually with old manure. *Prop.*—Division when foliage fades.

Coreopsis.—The hardy annuals are found in catalogues under "Callipsis," and all will thrive in ordinary soil. The flowers are mainly bright yellow, and many are good for cutting. *See* **Annuals.** Similarly, the perennials have the same predominant colour and are useful because of their long flowering season and abundance of flower. *Prop.*—Division.

Cornflower.—*See* **Centaurea.**

Cosmos.—Tall-growing, half-hardy annuals that are best grown in full sun in a dryish border. The large, daisy-like flowers can be had in a variety of colours, including white, yellow, pink, and crimson. *See* **Annuals.**

Cotoneaster.—Hardy evergreen and deciduous shrubs or small trees bearing scarlet or sometimes yellow berries in the autumn. All may be grown in ordinary or poor soil and planted in open or shady shrubberies and trailing species used against walls, over banks, or as ground cover. For shrubberies *C. lacteus* and *C.* 'Cornubia' with red berries and *C. rothchildianus* with yellow berries are among the best sorts; *C. conspicuus* 'Decora' is a strong grower for banks, while *C. horizontalis* is an excellent cover for any wall. Planting may be done in the autumn or spring, and no pruning, apart from occasional shaping, is required. *Prop.*—Seeds and layering.

Crataegus (Hawthorn).—There are many good varieties of our British hawthorn, *C. oxyacantha*, worthy of attention, particularly 'Coccinea' (crimson) and 'Paulii' (double, red). All will do well on poor soils, and no pruning is required. The common hawthorn makes a stout, impenetrable hedge planted 9 in. apart in a double row 9 in. asunder. *Prop.*—Common sort by seed; choice varieties by budding.

Crocus.—A hardy bulb of great beauty which was studied for many years by one of the greatest horticulturists of the twentieth century, the late E. A. Bowles. Does best in rich soil planted in bold groups around margins of beds or borders and naturalised in grass. When required, feed in early spring with bone meal at 2 oz. per sq. yd. *C. sieberi* and *C. tomasinianus* very early flowering; large-flowered, garden forms about three weeks later. *C. zonatus* flowers in the autumn and is often naturalised in grass. *Prop.*—Clumps may be lifted and divided about every five years, in July. The so-called autumn crocus is *Colchicum autumnale*. This bears large, lustrous leaves in the summer, followed by mauve or white flowers—of fleeting duration—in the autumn.

Crown Imperial.—*See* **Fritillaria.**

Cyclamen.—*See* **House plants.**

Cytisus (Broom).—Only does really well in dry, poor soils in full sun; choice, procumbent sorts, like *C. kewensis*, used in rock gardens and tall ones in open shrubberies. Pruning is important; shoots should be shortened after flowering, but old wood must never be cut. *Prop.*—Seed and cuttings in August in a sandy soil.

Daffodil.—*See* Narcissus.

Dahlia.—The cultivation of this plant is a special study, and there are probably more garden varieties of it than any other plant. Ordinary soil enriched with manure and an open position is required. Tubers may be planted 3 in. deep in April or young plants in late May. During the summer feed with soot water and liquid manure. After the first frosts lift, dry, and then store tubers in peat or straw in frost-proof place. Many stocks of dahlia are affected by virus (T30), and purchasers should be careful to check source of supply.

Daphne.—Shrubby plants, giving some of the most richly scented of all flowers. In particular, there is *D. mezereum*, which requires a damp soil; failure with the shrub is due usually to root disturbance or virus disease (T30) *D. odora* is one of the evergreen, fragrant species. Some references have suggested that this lovely shrub is not hardy, but there is no evidence to support the supposition. *Prop.*—Seed or layering.

Delphinium.—Hardy annuals and perennials. The latter sorts have gained popularity enormously since the War, due in the main to the activities of the Delphinium Society but also to the introduction of many very fine new varieties. American hybrids, like the 'Pacific Strain,' are very large but tend to die out and, consequently, lack the true, perennial habit of European sorts, albeit some of these have been weakened by the introduction of poor lines. It is important therefore to select stocks of strong constitution. Delphiniums need a deep, rich soil and a sunny position protected from wind. Plant in autumn 3 ft. apart, feed in the summer with liquid soot water, and mulch with decayed compost or manure in the spring. When growth starts, thin out weak growths to leave not more than five stems per plant. In winter take steps against possible slug damage (T28), and on this point it is beneficial to protect crowns with a covering of ashes. *Prop.*—Cuttings in the spring or seed; division of clumps is a poor alternative.

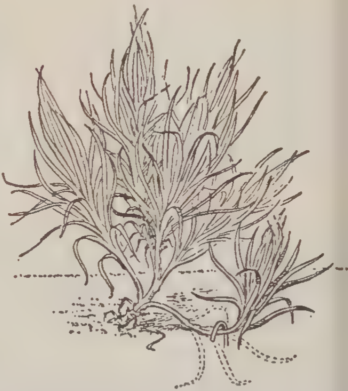
The hardy annual sorts are the well-known larkspurs, which grow to a height of 18 in. to 2 ft. and may be found in a range of colours including pink, red, white, and shades of blue. *See* Annuals.

Deutzia.—Hardy deciduous shrubs thriving in any soil and valuable for their summer flowers of white or whitish-pink shade. To keep the plants vigorous, shoots should be shortened after flowering and old or weak wood cut out. *D. scabra* is of robust habit, reaching about 7 ft., and *D. elegantissima* 'Fasciculata' proves a graceful shrub some 5 ft. tall with clusters of about twenty flowers coloured rosy-pink and each nearly an inch across. *Prop.*—Cuttings made from firm young growths about 10 in. long in sandy soil out-of-doors.

Dianthus.—This name covers a wide range of annual, biennial, and perennial plants. At one time often grown for their fragrance, but to a large extent this has been lost with the introduction of wider ranges of colour. Border carnations and picotees grown out-of-doors need a limy, fairly rich soil in full sun. Plant in the autumn or spring and, as the buds appear, feed with soot water or liquid animal manure, if necessary. These groups are *not* of good perennial habit and should be propagated annually to ensure continuation of stock.

The common pink requires the same soil conditions, and should be propagated when the stock gets weak; good scented varieties should be sought, and include the 'Imperial Pinks,' 'Mrs. Simkins,' and 'White Ladies.' *Prop.*—The best method is by layering in July so that the new plants can be put in their flowering position by mid-September. The lower leaves are pulled off selected shoots and a slit passing through a joint is made in the stem. Each layer is then pegged down with a hair-pin, the pin being placed above the cut. The layers are then covered with an inch of sandy compost and well watered.

In this genus is the sweet william; althou
truly a perennial, it is generally grown as a bi
nial and, consequently, the plant is raised fr
seed in May out-of-doors. In gardens where i
prone to rust disease control is most difficult a
it is not worth a place.



Layering Carnations—This is a typ
example of how many plants can be p
pagated. A strong, new growth is peg
down into sandy soil after a cut has b
made in the stem, at the point of peggi
Once rooted the layer can be severed fr
the parent and transplanted a week or t
later.

Digitalis.—The biennial sort generally found
gardens is the common foxglove, which is gro
in light shade in fairly rich, moist soil. In
past many named forms have been offered in
trade, but undoubtedly the best one is *D.* 'S
ton's Excelsior.' *Prop.*—Seed sown in May o
of-doors.

Doronicum.—Hardy perennials with yel
flowers; warrants wider planting, as they
among the earliest perennials to bloom and
thrive in poor soil or in some shade. The bes
D. austriacum flowering in March, height 9
Prop.—Division after flowering.

Echinops.—Name appropriately derived fr
echinos, a hedgehog, in reference to the spiny, l
scales of the flowers. The plant does well in
open position, where the globular heads of ste
blue flowers can be seen to advantage. *Prop*
Division in March, but best left undisturbed
long as possible, as it must be moved with care

Elaeagnus.—Hardy deciduous and evergr
shrubs generally grown in rather dry position
foliage plants. Of the evergreen sort, *E. pun*
'Aureo-Variegata' has bright golden variegat
and is therefore valuable for indoor decorat
during the winter. *Prop.*—Layering in
summer.

Erica.—The heathers are native plants
Britain, and many variants found in the wild h
been introduced into gardens to good purp
Indeed, heathers have become so popular t
special Heather Gardens have been made, and
fine examples may be found in the Royal Gard
Windsor, where the planting is new and the Ro
Horticultural Society's Gardens, Wisley. B
different sorts reaching the dimensions of sm
trees, dwarf kinds, and many scores of interes
variants, to supply flower throughout the y
will be found.

The Scottish heather is, botanically, *Call*
vulgaris, and, like all British heathers, it is into
ant of lime or chalk. Where alkaline condit
exist, planters can try *E. carnea*—a winter-flow
ing heather—or *E. darleyensis*, but the res
are usually disappointing. When planting
heathers, clumps must be well firmed and af

rds kept moist; subsequently, mulch all types nually with peat. *Prop.*—Division and layering.

Erigeron.—Hardy perennial for sunny borders; isy-like flowers freely develop and are good for tting. *Prop.*—Division in the autumn.

Escallonia.—Slightly tender evergreen and deci- ous shrubs. In the Midlands protection of a ıth wall is necessary; suitable for open shrub- ry in the South. Ideal for maritime conditions, d here may be used to good effect as hedges. ıny of the best varieties originated in the rsery of Messrs. The Slieve Donard Co. in unty Down. *Prop.*—Cuttings under a glass jar summer; layers in September.

Eschscholzia californica.—A hardy annual of sy culture; height 18 in., flowers mainly shades orange. *See* Annuals.

Everlasting Flowers.—*See* Helichrysum.

Ferns.—A large number of plants are included der this name and, as they grow wild in many rts of the world, some need hothouse conditions. ey are distinguished from flowering plants by eir method of reproduction; instead of produc- seeds, ferns develop spores, usually on the ck of their leaves. The hardy kinds may be own in equal parts of leaf-mould and soil, and fronds of leaf-losing kinds should not be noved until the spring, as they offer some otection from the cold. Tender ferns should be otted when new growth starts in the spring a compost of equal parts soil, leaf-mould, and ıd, using a pot just large enough for the purpose. ring the growing season, in particular, keep the ts moist and plants free from a dry or smokey nosphere. *Prop.*—Division of clumps when wth starts in the spring.

Forget-me-nots.—*See* Myosotis.

Forsythia.—Commonly found in many gardens, it is of easy culture in any soil. Flowers ght yellow in early spring. To keep in good pe prune directly after flowering by cutting out wood. *F. intermedia* 'Lynwood' is upright growth and *F. suspensa* of weeping habit; h types make good wall plants for North ects. *Prop.*—Cuttings in the autumn.

Foxglove.—*See* Digitalis.

Freesia.—Greenhouse bulbous plant and, if wn for scent, care must be taken to select grant varieties. Pot in the autumn in a fairly compost and keep as cold as possible until wth is seen. Then bring into a frost-free enhouse and water freely. When flower stems pear, feed with liquid manure; after flowering, dually dry-off until time for repotting. lures almost invariably traced to premature cing before root growth has been made or wing in excessively high temperature. *Prop.*— sets at potting time.

Fritillaria.—The one mainly used in gardens is *imperialis*, a handsome, spring-flowering bulb. grow it *really* well, this species must be given a p, rich soil and, contrary to some views, it is lifted every year as soon as the foliage fades. rowth is poor or plants do not flower, feed when wth starts in the following spring with equal ts of bone meal and superphosphate at 3 oz. sq. yd. *Prop.*—Offsets removed from parent at lifting time. The old bulb should then be anted at once and any offsets lined out in a sery row.

uchsia.—Greenhouse and tender flowering ubs. The outdoor sorts (of which *F. riccartonii* ne best) may be grown in light soil in full sun. the spring prune all growth down to ground l; protect, if necessary, in winter with cover- of cut bracken or dry straw. Greenhouse ieties are potted firmly before growth starts in spring and, when buds burst, all the previous r's growth can be cut back hard. To encourage vering, feed with a liquid manure, such as dried od, and syringe foliage in hot weather. During winter keep plants dry and house in a cool greenhouse. *Prop.*—Cuttings of new growth taken about 1 in. long and inserted in sand under a bell jar.

Gaillardia.—Hardy annuals and perennials 18 in. to 3 ft. high which bear large, richly coloured flowers invaluable for cutting in mid- and late-summer. Unfortunately, on heavy soil the perennials are liable to die after flowering, and even on well-drained soils they cannot be considered long-lived plants. *Prop.*—Normally it is necessary to raise a fresh stock in alternate years; seed is sown in May in a cold frame and the young plants lined out in a reserve border prior to planting in the autumn.

Galanthus (Snowdrop).—Hardy bulbs well worth growing if given a moist, shady position where stock can be left undisturbed. Planting should be done in fairly bold clumps; bulbs are not expensive, and many variants, like double-flowered and tall-stemmed ones, are well worth a trial. *Prop.*—Lift and divide clumps in August.

Gentiana.—The gentians comprise some of the most fascinating of all rock-garden plants partly, perhaps, because some are difficult to manage. In particular, *G. acaulis*—which has true "gentian blue" flowers—is exacting in its requirements, and in many gardens flowering can never be induced. What controls flowering has not been discovered, and the plant can be grown well in acid or limy soils. On the other hand, *G. sino-ornata* must have an acid soil and is best in a position out of the direct sun. Beginners with the genus are advised to start with easily grown sorts, like *G. lagodechina* and *G. septemfida*. *Prop.*—Seed sown in cold frame in March or division in early spring.

Geranium.—The true geranium or cranesbill is a hardy floriferous perennial for rock garden or open border. In the latter case *G. ibericum* (blue flowers) and *G. sanguineum* 'Lancastriense' (rosy-pink flowers) are exceptionally good, and both do well in dry, sunny positions. The so-called "bedding" or "greenhouse" geranium is a pelargonium (*q.v.*). *Prop.*—Seed in March.

Gladiolus.—Dutch hybridists have done much work on this bulbous plant, and many new and lovely varieties are now available. The plant is responsive to good cultivation, and corms may be planted 4 in. deep and 6 in. apart during the spring in well-prepared ground. When the blooms fade remove the dead spikes of flower and lift the corms in September. After a month—and this point is important—pull off the old shrivelled corm and clean the new one. By doing this there is less likelihood of spores of diseases overwintering on the new stock. Finally, the corms should be stored in a dry, frost-free shed, and if given proper attention can be kept for a number of years. *Prop.*—Bulbils, removed when the corms are cleaned, can be sown in the spring in nursery rows and will flower within two years.

Godetia.—Hardy annual of easy culture and tolerant of poor soil conditions and even some shade. There are many varieties, mainly with bright flowers of rosy-pink and crimson. *See* Annuals.

Guernsey Lily.—*See* Nerine.

Gypsophila.—The favourite sort is *G. paniculata*, which is often grown for cutting, together with its double-flowered form, 'Bristol Fairy.' To do well gypsophila must be given a dryish soil which the roots can penetrate undisturbed; if growth is poor mulch in the spring with animal manure. *Prop.*—Generally done by seed in spring; special forms by grafting.

Hamamelis.—A lovely, but little grown, winter-flowering, heavily-scented shrub. The delicate, lemon-coloured flowers appear interminably from December to February. Although it flowers in its young stage, hamamelis is slow to get established and must be left free of root disturbance. The best sort is *H. mollis* introduced from China in 1879. *Prop.*—Usually by grafting; can be layered.

Heather.—*See* Erica.

Hedera.—Although ivy is seldom planted nowadays, there are a few evergreens to equal it for covering buildings. The large-leaved ivy with golden variegation, *H. colchica* 'Dentato-Variegata,' is invaluable for cold or shady walls. *Prop.*—Cuttings in August in shady border out-of-doors.

Helianthus.—The perennial sunflowers are tall, yellow-flowered plants of vigorous habit. They spread quickly and become a nuisance, and therefore clumps should be lifted and single, rooted pieces replanted every other year. The annual sunflower may reach a height of 10 ft. or so; seed is sown out-of-doors in April or seedlings raised under glass in the spring. When the flower bud appears, feed with soot water. The seed may be used as food for large birds like parrots.

Helichrysum.—Although this is a large group of plants, the most interesting is the half-hardy annual, *H. bracteatum*, the everlasting flower. When the flowers are fully developed they are cut with long stems and hung up to dry for winter decoration. *See* **Annuals.**

Heliotropium peruvianum (Cherry Pie).—Scented, shrubby plants used for greenhouse decoration or summer bedding. *H.* 'Sir Edward Fry' is among the scented varieties and *H.* 'Princess Marina' is the best dark-purple variety. For really good results, heliotropes need a rich soil and plenty of water in summer. *Prop.*—Cuttings 2–3 in. long in early autumn or spring, struck in sandy loam in a warm greenhouse.

Helleborus.—The Christmas rose, *H. niger*, should be planted out of the direct sun in a moist soil which has been liberally enriched with leaf-mould and old manure and here left free from root disturbance. Its large, white flowers appear irregularly from December to February with early flowering encouraged by protection with cloches. The Lenten rose, *H. orientalis*, flowers from February to April, and it is well worth searching nurserymens' lists for varieties with a wide range of colours. *Prop.*—Division of clumps in the spring, with each piece having four or five growth buds; the clumps should not be split into small pieces.

Hemerocallis.—Hardy perennial for moist border either open or slightly shaded. Mulch established clumps in the spring with compost or manure. Many new varieties are coming on the market as a result of introductions from America, where the plant is popular. *Prop.*—Division.

Hibiscus.—The evergreen, shrubby sorts with large exotic flowers are widely grown in the tropics and can be seen under glass in botanic gardens in Britain. *H. syriacus* is a deciduous, hardy species; little pruning is required, and in full sun it will reach 8–10 ft. Normally, it is a free-flowering plant of great beauty and, in cases where the flowers fail to develop, the stock is best replaced with good varieties, like 'Coeleste' (single, blue) and 'Woodbridge' (single, red). *Prop.*—Cuttings under glass; grafting.

Holly.—*See* **Ilex.**

Hollyhock.—*See* **Althaea.**

Honeysuckle.—*See* **Lonicera.**

House Leek.—*See* **Sempervivum.**

Hyacinth.—Bulbs generally used for bowl culture; often results are disappointing, but responsibility does not necessarily rest with the nurseryman, as poor cultivation is the most probable cause. Plant in September–early October (not later) in peat, loam, and sand, and keep as cool as possible until growth starts, when bowls may be brought into a warm room. Care must be taken with watering, as the bulbs must not dry out nor the compost allowed to become wet and soggy. After flowering, plant out-of-doors and lift annually in June for replanting in the autumn; for bowls a fresh stock is required every year. Failures are mostly due to late planting or faul
watering.

Hydrangea.—A favourite shrub introduced fro
the Far East. Of the many forms, the one offere
by florists, *H. macrophylla*, is the most popula
This can be bought in a wide range of shade
from white and pink through to crimson and blu
The colour will depend on soil reaction; in alkali
or neutral soils *only* white and pink shades can
grown, and blue flowers will be found *only* on ac
soil. The intensity of colour can be improved
adding lime in the first instance and flowers
sulphur in the second, but it is not possible
make an alkaline garden soil acid in reactio
Lack of flower is generally the result of buds bei
killed by cold weather. For this reason, hydra
geas are best not pruned until the late sprin
then old flower-heads and any weak or unwant
growth can be cut out. During the summer t
plants must not suffer from lack of water.
Among the many other sorts are *H. paniculat*
with large, cone-shaped panicles of flower a
H. petiolaris. The latter plant is a vigoro
climber, well suited to cover cold walls or f
climbing over dead trees. *Prop.*—Cuttings
July–August in a cold frame.

Iberis (Candytuft).—The hardy annual sorts w
thrive in any soil, and may be had in a range
colours. *See* **Annuals.** The perennial candytu
(*I. sempervirens*) is a good plant for a rock wa
and has white flowers in early spring. *Prop.*–
Seeds in spring and cuttings in summer.

Ilex.—The ornamental value of our nati
holly is rarely fully appreciated, bearing in mi
that, on good varieties, the berries sometimes pe
sist until March. The greenish flowers are som
times bisexual, and sometimes male and fema
flowers are on *separate* plants. For this reas
hollies should be planted in groups, and at lea
one plant of good berrying habit, like *I. aquifoliu*
'Pyramidalis,' grown. Some varieties ha
yellow berries and gold or silver variegations
their leaves. *Prop.*—Seed; special forms
budding.

Iris.—This plant is divided into two main se
tions: those types which grow from bulbs a
those which grow from fleshy rhizomes, with ma
subdivisions in each of them. Of the latter typ
there are the commonly grown bearded flag iris
which, owing to their ease of cultivation and wi
range of colours, are appropriately known as t
poor man's orchid. Notwithstanding, these iris
respond to good treatment, doing best in well-d
soil to which a little manure has been added and
dressing of rough chalk forked into the surfa
The site should be in full sun for preference a
one that never lies wet in winter. Planting
division of established clumps is done in Ju
setting the rhizome on the surface of the soil b
firming the roots well. To maintain growth a
flower, feed annually in the spring with equ
parts of superphosphate and bone meal at 3–4
per sq. yd. Iris gardens are not often seen now
days, but the fine example still maintained at Ke
is well worth close inspection.
In the bulbous section the Siberian iris is
graceful plant with delicate foliage, though mu
smaller-flowered than the flags. They make
fine waterside planting or may be grown in t
herbaceous border. The Japanese iris is anoth
water lover, and this has delicate-coloured, clem
tis-like flowers. On the other hand, for dry, po
stony soils in full sun the lovely, winter-floweri
Algerian iris, *I. unguicularis* (*stylosa*), is an ide
plant, flowering as it does in December a
January. This is a plant which must be left u
disturbed after planting in June and if lea
growth is excessive the foliage can be cut back
half in August. Spanish, Dutch, and Engli
types of bulbous iris are often used as cut flowe
These may be planted in ordinary garden soil
the autumn and left undisturbed until signs
deterioration are found.

Japonica.—Common misnomer of *Chaenomel*
(*q.v.*).

Jasminum.—The yellow-flowered, swee
scented winter jasmine blooms intermitten

m November to February. It grows in any , and is best trained up a wall or grown on a lis. Pruning consists of cutting out the flower-shoots as soon as the blossoms fade. The nmer jasmine is a vigorous climbing plant with ite, scented flowers. It needs a sunny position l should be well thinned after flowering. *op.*—Layering in summer.

Kalmia.—Hardy American shrubs with clusters waxy, rose or pink blossoms in early summer. hough slow to get established and requiring a np, acid soil, the plant is well worth growing. constitutes a feature of the gardens of the tional Trust at Sheffield Park, Sussex. *Prop.*—d or layering.

Kerria japonica.—A hardy shrub which will ive in any garden but is best fed with manure encourage strong growth. When the yellow vers fade, the stock should be kept vigorous cutting out old or weak growth. The plant named after William Kerr, a young man patched from Kew to collect plants in China. *op.*—Division in autumn.

Kniphofia (Red-hot Poker).—Although these nts are so commonly seen, their full value as -flowering subjects is not often fully explored. ere are a number of good varieties worth grow- , such as 'Maid of Orleans' (white, 4 ft.), ount Etna' (scarlet, 5 ft.), and 'Royal Stan- d' (gold and scarlet, 4 ft.). Of equal value is dwarf variety with grass-like foliage, *K. onii*. *Prop.*—Division in March; easily raised n seed if so desired.

aburnum.—Handsome trees with long racemes yellow flowers the seeds of which are very sonous. It is not advisable to remove branches, wounds do not heal well or quickly, and once pecimen shows signs of deterioration it is best aced with little delay. *Prop.*—Seed or graft-

arkspur.—*See* Delphinium.

athyrus (Sweet Pea).—For general garden de- ation, seed may be sown in pots in a warm enhouse in early February prior to transplant- out-of-doors in April. When heat is not ilable sowing can be done in the open in Octo- setting the seed 4–6 in. apart and 2 in. deep re the plants are to grow. In this case the s are best protected by cloches. As the plants er with great freedom and make strong growth, ch, deep soil is required. During the summer er should be given freely and liquid animal ure or soot water applied weekly when flower- starts. When raised for exhibition, special ural treatment is necessary. The cause of the lition referred to as bud drop is not known, it is thought to be connected with low tem- ture and faulty root action.

here is also the hardy, perennial sweet pea, an world plant usually seen at its best in cottage lens. This plant requires the same cultural litions, except that the old stems are cut down ne autumn. Three or four different species are lable, and all are easily raised from seed sown he spring.

avandula.—The lavender is one of the best vn of garden plants. It thrives in full sun light soil; old flower heads should be clipped n the summer, but any cutting back into old vth must be left until the spring. The best en form is *L. spica* 'Nana Atropurpurea'; as a neat, dwarf habit, with deep purple ers, and is available from leading nurserymen. .—Cuttings out-of-doors in August–Septem-

ucojum.—The spring snowflake flowers in uary and is a charming plant for any damp, y border. Although it has a large flower, it never become as popular as the snowdrop, ite its ease of culture. It should be grown everyone who values early spring flowers. .—Lift clumps and replant after removing ts in August.

ac.—*See* Syringa.

Lilium.—The lilies constitute a large genus of plants, some of easy culture, some demanding the most exacting of conditions. For a soil containing chalk two of the best lilies are *L. candidum*, the Madonna lily, and *L. regale*. The former is a feature of many gardens in South Wales, where bulbs are planted near the surface of the soil and the clumps eventually left to develop undisturbed. Only the easiest-grown lilies are suitable for the herbaceous border and, here, apart from the Madonna lily, the tiger and martagon lilies should be first choices for beginners in the cultivation of this genus. *Prop.*—Those referred to above may all be raised from seed sown out-of-doors (or in deep boxes in a cold frame) in the spring. In the following April line out into nursery rows prior to transplanting to flowering positions. Also propagated by offsets and bulbils.

Lily of the Valley.—*See* Convallaria.

Lobelia.—The bedding lobelias are perennial plants best raised as annuals (*q.v.*). They do well in a light soil, but should be firmed at planting time to prevent plants dying off during a hot spell. The handsome, tall-growing lobelias with scarlet flowers, like *L. fulgens* 'Huntsman,' may be used in herbaceous borders with great effect, but the roots must be lifted and overwintered in a cold frame. These sorts grow to a height of 2–3 ft. and will do well only on a wet, heavily manured soil.

Lonicera.—The honeysuckles make effective climbing plants if grown on the shady side of arches or tree stumps or against north or west walls. Care should be taken to train young growth before it becomes hard. Old shoots may be cut out each spring to keep the plant within bounds, although space must be available for free development. If growth and flowering is poor mulch the roots in the spring with old manure. *Prop.*—Easily done by layering in late summer.

Lupins.—There are two sorts of lupins, perennial and annual. The herbaceous perennials are among the most colourful of plants as a result of the famous 'Russell' strain being introduced. Of late years, however, the constitution of the plant has been weakened through, perhaps, breeding and virus diseases, and it should be taken for granted that most stocks have to be replaced every two years or even annually in some cases. The plant requires a rich soil and is best in ground free of lime. Conversely, in poor soil the tree lupin thrives and will reach a height of 7–9 ft.; plant in full sun and lightly prune into shape after flowering. *Prop.*—Both sorts are best raised from seed sown in May out-of-doors and transferred to flowering positions in October. The annual lupin may be obtained in a range of colours, and should be grown in full sun. *See* Annuals.

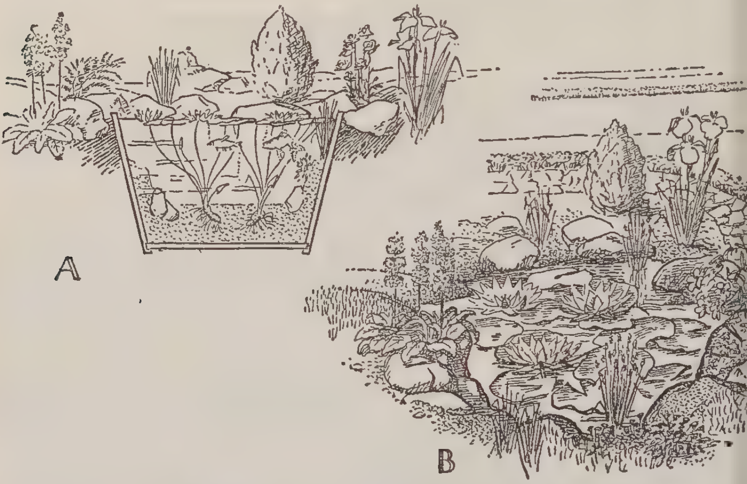
Magnolia.—Rightly said to be one of the most beautiful of all flowering plants. Contrary to popular belief, some kinds are of easy culture, flowering when young and suitable for small gardens. Of course, careful selection is necessary and for a specimen on a lawn *M.* 'Soulangeana' (large, white or white, purple-stained flowers) is ideal. *M. stellata* freely flowers in the young stage, and may be planted in an ordinary border if the soil is lime free. To encourage growth, mulch annually with peat or leaf mould, but never dig near the roots. The evergreen magnolia is often seen as a fine wall plant in old gardens. This is the only species which may be pruned, and long shoots can be cut back hard in April. There are a number of non-flowering strains of the evergreen one, and unsatisfactory plants are best destroyed, as flowering cannot be induced; in buying a replacement care is necessary in order to avoid *another* dud. *Prop.*—Seed sown as soon as it is ripe in October; layering.

Mahonia.—Hardy evergreen shrub. *M. aquifolium* is useful as ground cover, and will thrive in any soil and in any cold, shady position providing the soil is not waterlogged. *M. japonica* has long racemes of lemon-scented flowers in the winter; inferior sorts are often offered by nurserymen under this name. *Prop.*—Seed, suckers, and layers.

Marigold.—*See* Calandula.

Mathiola.—The night-scented stock is a hardy annual with insignificant purplish flowers which open at dusk; grown primarily for its perfume. Conversely, the so-called Ten-Week stocks and a selection of these, the East Lothian stocks, have a wide range of colours. If sown in March they may be used for summer bedding or if sown in August overwintered in a sunny frame and grown as a biennial.

Brompton stocks flower earlier than the other sorts, and are grown as a biennial by sowing seed in June or early July and, after pricking out into boxes, are overwintered in a sunny frame. In mild districts, if the soil is well drained, stocks may be planted out-of-doors in the autumn, but a reserve should be kept for filling up gaps in the spring.



WATER LILIES IN TUBS—Drawing (A) shows a cross-section with correct percentage of water a soil together with water lilies and fish. Drawing (B) illustrates marginal planting with primul Japanese irises, and a dwarf coniferous tree.

Meconopsis.—This genus includes the famous "blue poppy," introduced from the Himalayas. It is not a plant of easy culture, albeit large groups are grown in many woodland gardens where soil conditions permit. After flowering the plants generally die, although an occasional plant may persist. *Prop.*—Seed sown in March.

Michaelmas Daisy.—*See* Aster.

Montbretia.—This bulbous plant is of easy culture and has a long season of flowering. Many new varieties with large flowers are now available, and growth can be kept vigorous by lifting and dividing the clumps every three or four years. Plant in early spring 4 in. deep and 6 in. apart and in cold gardens protect clumps in winter with a covering of ashes.

Myosotis.—The forget-me-not is grown as a biennial by sowing seed in May and planting out in the autumn in conjunction with spring-flowering bulbs and wallflowers. Poor varieties freely establish themselves, and these should be destroyed before planting any of the really good sorts offered by seedsmen.

Narcissus.—This botanical name includes plants commonly known as "daffodil" and "narcissus." Although often grown, the wide garden value of these spring-flowering bulbs is not fully realised, as by careful selection of varieties a long season flower can be obtained when they are grown formal borders or naturalised. Thus, a seas may be extended with 'Peeping Tom' a 'Covent Garden' (early) and 'Geranium' a 'Buttermilk' (late). The bulbs can be left u disturbed until flowering is affected by over-crow ing; the clumps should then be lifted and divided in the late summer. To maintain vigo feed annually in February with 2 parts bone me 1 part hoof and horn meal, and 1 part sulpha of potash at 2 oz. per sq. yd. The chief troub with narcissi are due to eelworm (T29) and t narcissus bulb fly (T28). For indoor work, pla in bowls in October and keep in cold place un growth is an inch high; failure is invariably d to premature forcing or faulty watering.

Nasturtium.—*See* Tropaeolum.

Nepeta (Catmint).—In recent years this edg plant with silvery foliage and mauve flowers become increasingly popular. When flowering mid-summer there is no finer display of colo It grows freely on any light, well-drained soil full sun. The best sort is *N. faassenii*. *Prop* Division of clumps in March.

Nerine.—Lately this lovely bulbous plant increased in popularity mainly through the var ties introduced from the late Lionel de Rot child's garden at Exbury. The hardy sort *bowdenii* flowers in the autumn and should planted at the foot of a warm wall in August September and left undisturbed for many yea As the bulbs gradually multiply and work to surface, a light dressing of sandy compost, which has been added a little bone meal, can applied. *Prop.*—Separation of bulbs in Augus

Nicotiana (Tobacco Plant).—This half-har annual is grown mainly for its heavily scen flowers, which open in the evening. It is wo remembering that the white-flowered sorts are best in this respect; scarlets and pinks are v much inferior. *See* Annuals. The tobacco commerce is a different plant, namely, *N. tabac*

Nymphaea.—No branch of gardening is m fascinating than the water garden, and for it chief plant must be the water lily. Basically, main reason for failure is in the fact that in m pools the *average* depth of water is less than 18 this means that the water is liable to be advers ected by extremes of temperature. All nym- heas should be grown in full sun and where the ter is still; in streams it is necessary to utilise little backwater out of the current. Water es are planted in May in large wicker baskets h a compost of three-quarters of loam and a arter of peat; alternatively, planting sites can built up with bricks to the desired height. If wth is poor, mould Clay's Fertiliser into the e of pigeons' eggs and drop one around each mp. To maintain a healthy condition in the ter, fish should be introduced as soon as the nts are established. *Prop.*—Division of tuber- s roots in late May.

Orchids.—In the main, this large group of plants eds greenhouse conditions and specialised know- ge. Their cultivation has attracted the atten- n of some of the greatest of horticulturists, and ailed references may be found in books like *chids, their Description and Cultivation*, by H. Curtis (Putnam), 1950.

Paeonia.—There are two sorts of paeony, the e paeony and the herbaceous paeony. The mer needs a sheltered, warm position and takes out three years to flower from planting time. e latter sort needs a moist, rich soil, and should mulched annually in the spring with well- ted manure; some are known not to flower, d as such plants cannot be induced to do so ey should be destroyed. The old-fashioned riety of paeony has been superseded by many e new varieties found listed by specialists. *op.*—Tree paeonies by layering or seed sown in e autumn; herbaceous sorts by seed or division.

Pansy.—*See* Viola.

Papaver (Poppy).—The oriental poppy is a rdy herbaceous perennial with striking flowers, olerant of shade and root disturbance. As it oms early, it should be set near the back of a rder, as the large leaves look untidy later in the ar. Apart from the commonly grown, red- wered sort there are others in shades of crimson, k, and lavender. *Prop.*—A wide range of ours can be obtained by sowing mixed seeds May. This is a better method than division. e Shirley poppy is a hardy annual (*q.v.*), while *nudicale* is a biennial needing a warm, sheltered sition.

Parthenocissus (Virginia Creeper).—This nber, with its brilliantly-coloured leaves, makes ne sight in the autumn, and there is no better nt for covering brickwork or unsightly build- s with a south or west aspect. It has been gested (mainly by builders) that the plant will nage stonework or cause dampness. There is le evidence to support these suppositions, and sons for damage can usually be traced—often hout difficulty—to other sources. The plant had a number of names—*Ampelopsis veitchii* one—but up-to-date nurserymen are listing it rectly as *P. tricuspidata*. *Prop.*—Cuttings -of-doors in the late summer; layering.

Passiflora caerulea (Passion Flower).—A south l in favoured gardens is needed to grow this nt. It is of vigorous habit and, once the frame- rk of branches has been produced, it should be ned annually in the early spring, by cutting k all the previous season's growth to 2–3 in. the main stem. *Prop.*—Layering.

Pelargonium (Geranium).—So-called "bedding aniums," such as 'Paul Crampel,' are really al pelargoniums. To maintain a stock, take tings in early August and insert in sandy soil und the edge of a pot and overwinter in a st-free greenhouse. In the spring pot-up singly use for bedding. Otherwise pot-on after two nths and, if early buds are nipped off, plants be adopted for late flowering indoors. Pelar- iums are easy to grow, but for best results a ition in full sun is necessary, and cuttings uld be rooted *before* the autumn so that over- tering constitutes no great difficulty.

Petunia.—Although really perennials, these nts, native of South America, are treated as uals (*q.v.*). They are sun lovers and do best on light soils. Petunias make fine plants for sunny window boxes, and particularly happy combinations can be made by planting together varieties such as 'Violacea' (deep violet) and 'Cheerful' (pale pink) or 'Flaming Velvet' (crimson) and 'Cream Star' (pale cream). The violet-flowered sorts are faintly scented.

Philadelphus (Mock Orange).—Although some fine varieties of this shrub are available in the trade, it is not grown as widely as its merit deserves. As a scented shrub it has few equals, while it is tolerant of poor soil conditions and shade. Particularly good sorts worth searching for are 'Albatre' (double), 'Beauclerk' (single), and 'Sybille,' which, at 3 ft., is about half the height of the others. After flowering, prune annually by removing as much old flowering wood as possible. *Prop.*—Hard-wood cuttings out-of-doors in November.

Phlox.—A wide range of varieties of the border phlox are offered to make an impressive display late in the season. If grown on light soils some shade is desirable, as phloxes do well where only the soil is damp. For this reason, mulching should be done annually in the spring with compost or animal manure. Failures are usually due to eelworm (T29). *Prop.*—Seeds in autumn; division.

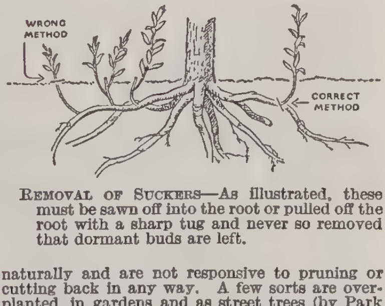
Poppy.—*See* **Papaver.**

Polyanthus.—*See* **Primula.**

Polygonum.—In the main these plants are weeds of gardens, although originally they were introduced from the Orient for ornamental purposes at a time when their invasive habits were not fully appreciated. The one woody climber in the genus, *P. baldschuanicum*, makes an admirable cover where a very vigorous plant is wanted. Rampant and unwanted species may be eradicated by hormone treatment (T33).

Primula.—Polyanthuses, primroses, greenhouse primulas, and the hardy primulas all belong in this genus. The first two are the most popular; both will do well only in damp soil and respond to generous manurial treatment; both are available in a wide range of colours. *Prop.*—The Blackmore and Langdon strains of seed will give a magnificent display of mixed colours. Sow in warm greenhouse in early March or cold frame in April; prick out into boxes and transfer to flowering positions in the autumn.

Prunus.—A large genus which includes the flowering peaches, Japanese cherries, and flowering almonds. All of them are best left to develop naturally and are not responsive to pruning or cutting back in any way. A few sorts are overplanted in gardens and as street trees (by Park Superintendents), but anybody wishing to be a little out of the ordinary would do well to see the wide range of some of these lovely trees flowering in April and May in our botanic gardens and many of the large gardens now under the jurisdiction of the National Trust. The selection offered by nurserymen is often strictly along conventional lines. Lack of flower in some seasons can often be traced to bird damage.

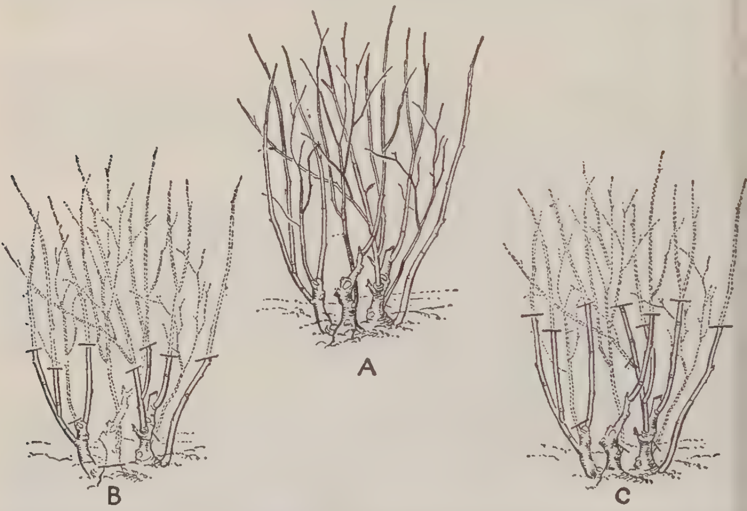


REMOVAL OF SUCKERS—As illustrated, these must be sawn off into the root or pulled off the root with a sharp tug and never so removed that dormant buds are left.

Red-hot Poker.—*See* **Kniphofia.**

Rhododendron.—Greenhouse and hardy, evergreen and deciduous shrubs, including *Azalea.* With something like ten thousand different sorts, it is impossible to deal with individual requirements. General cultivation; an acidic soil is essential, with adequate moisture in summer. If growth is poor on established plants, mulch liberally with animal manure. Beginners should plant from the accepted list of hardy garden hybrids. Since the turn of the century widely planted and fine examples are to be found, for instance, in many gardens of the National Trust. *Prop.*—Seed and layering.

Romneya.—Since its introduction from California in about 1850 the plant has proved a fascination to gardeners, as sometimes it fails completely or does exceedingly well. It apears to require a light soil and a sheltered position, preferably against a sunny wall, and there is no point in trying to grow a romneya on a heavy, wet soil. Usually the annual stems die off in the winter and may be cut down at ground level in the early spring; if persistent the stems can be cut back to sound growth. The new growth is susceptible to slug damage, and appropriate steps must be taken (T28). *Prop.*—Seed or suckers taken off in the spring.



Pruning Roses—(A) A vigorous unpruned plant. (B) The same plant pruned for the producti of exhibition blooms, (C) and pruned for garden decoration.

Rosa (Rose).—Undoubtedly the rose is the most popular of all garden flowers, and it may be found in a multitude of forms. The dwarf roses for bedding may be grown on most soils, but are best on a rich, heavy loam. Planting is done from early November onwards when soil conditions permit and the first pruning carried out in the following spring, when the extent of any winter damage can be seen. Opinions differ sharply on pruning; a sound, general rule is to do the work in March and—unless there are special circumstances—to prune on the light side. Thus, for Hybrid Teas and the like, reduce strong stems by about one-third of their length, medium ones by a half, and weak ones to within two or three buds of the main stem.

Whatever sorts of soil roses are grown in, feeding is important, but, of course, it is particularly so on poor ones. It is in soils of *low* fertility that diseases such as rust and black spot are most prevalent and, in some measure, persistence of the disease is due to bad cultivation and lack of treatment with fertilisers. Where black spot is established, spray with "Captan." For a manuria programme, an application of 2 parts of super phosphate and 1 part of sulphate of potash can b applied at 3 oz. per sq. yd. after pruning. Follow ing this, a surface mulch of animal manure, com post, peat, or leaf-mould or a mixture of all c them is given about 2–3 in. thick. Subsequentl if growth is poor, a dressing of nitro-chalk can b made at 1 oz. per sq. yd. Some other manuria treatments, like the so-called "Foliar Feeding and use of "special" (and often expensive) com pounds, have little to commend them

Where soil conditions are poor and diseas prevalent, it is important to buy plants only fro nurserymen who take special precautions to ensu that their customers have disease-free stoc Likewise, varieties of robust constitution a essential, and a selection list may include: *Hybr Teas:* 'Christopher Stone' (crimson), 'Dan Edith Helen' (pink), 'Eden Rose' (magen pink), 'Granmere Jenny' (yellow, rose-pi flush), 'Madam Henri Guillot' (salmon pink 'Quebec' (yellow), and 'Tzigane' (bicolo vermilion and yellow). *Floribundas:* 'Dain Maid' (rose pink), 'Dusky Maiden' (dark re 'Tantau's Surprise' (deep crimson), and 'Yello Holstein' (yellow).

In most of the modern hybrids scent is almo absent. The true rose perfume is found only the Old Fashion or shrub roses and, normall these are planted in a mixed shrub border. F the richest perfume varieties like 'Mrs. Jo Laing' and 'Conrad F. Meyer' should sought. *Prop.*—Nurserymen's plants are bu ded; many varieties are easily raised from cu tings taken in the autumn and struck in sandy s out-of-doors.

Salvia.—Annuals, perennials, and tender shrul The most popular one is the scarlet sort used f bedding. It requires careful attention, and se should be sown in February in a temperature 60° Fahrenheit and seedlings put into single p when large enough. Gradually the young plan are hardened off and finally planted out in ri soil in a sunny bed.

Saxifraga.—A large genus of plants suitable f the rock garden and valued for their bright flowe in the spring. The encrusted saxifrages s cushion-forming plants requiring sharp, surfa drainage and an open position out of the dire

The mossy saxifrages are mat-forming in
th and of easy culture. In time old clumps
lop brown patches and then require splitting
nd replanting in the spring.

abiosa.—The commonly grown perennial sort
caucasica and is invaluable as a cut flower.
not at home on all soils, and only does really
in a deep, rich loam containing plenty of
x. In addition, it must be grown in full sun
particular care taken against slugs. *Prop.*—
plants divided in the spring and rooted pieces
nted in their flowering positions. A wide
e of shades in white, blue, and purple can be
normally from sowing mixed seed in April.

dum.—The stonecrops make up a large group
rdy and tender plants, but comparatively few
of horticultural value. Notwithstanding,
m spectabile is to be found in most herbaceous
ers, where its fine, flat heads of pink flowers
a feature for many weeks. It is beloved by
and butterflies. *S. sieboldii* was introduced
Japan about 100 years ago and, although
y, it is usually grown as a house plant. In
vinter it can be stood out-of-doors, and every
or three years repotted in the spring; keep
watered during the summer and feed with
d manure occasionally. *Prop.*—Division in
spring.

mpervivum (House leek).—These hardy plants
succulent leaves often decorate the crevices
d walls and are regular features of trough or
gardens. If given a light poor soil and a
ion in full sun a fascinating collection of house
can be built up. The species which gives
plant its common name can be established
y on a sunny roof by planting in a mixture of
manure and clay during the spring. *Prop.*—
sion in the spring.

immia.—A hardy evergreen 2–3 ft. tall which
lerant of shade and some degree of dryness.
owth is poor water with a liquid manure and
h with peat or leaf mould. Some forms
only male flowers and to ensure a good crop
rries plant an hermaphrodite like *S. foremanii.*
.—Layering in the autumn.

owdrop.—*See* **Galanthus.**

owflake.—*See* **Leucojum.**

lanum capsicastrum (Winter Cherry).—A
ving plant with bright-red fruits which is
used for house decoration. To maintain
plant in a healthy condition it should be clear
aughts and fumes of gas fires and the foliage
fresh and free of dust by vigorous syringing.
e stock is to be kept for more than one season
r should be given only sparingly in the New
, and in early March all the side shoots pruned
hard to within a bud or two of the main
s. As new growth develops, water can be
more freely and syringing started when the
rs first appear; liquid manure will prove
ficial when berries develop.

iraea.—Hardy deciduous shrubs for open
ers; tolerant of poor soil conditions. The
nonly grown one is *Spiraea bumalda* (syn.
ica). After flowering, a percentage of the
vood should be removed together with any
growth, and development of new shoots
raged by mulching with compost or animal
ire. *Prop.*—Cuttings rooted in sandy soil
r a hand light in summer; suckers thinned
n winter.

ocks.—*See* **Mathiola.**

nflower.—*See* **Helianthus.**

eet William.—*See* **Dianthus.**

nphoricarpos (Snowberry).—Often found
ing in deep shade and in competition with
of overhanging trees, presumably as a result
e generalisation that the shrub is a shade
. Certainly a useful one in this respect, but
responsive to good treatment. Given an
ge soil and if growth is thinned annually in

the early spring, then *S. albus* 'Laevigatus' is well worth having. Its large white fruits are untouched by birds and hang well into the winter, and are thus beloved by the floral decorator. *Prop.*—Suckers removed in the winter.

Syringa (Lilac).—The botanical name of *Syringa* is often erroneously applied to the Mock Orange, correctly named *Philadelphus* (*q.v.*). A wide selection of first-class varieties are available in nurserymen's lists. To obtain heavy crops of flowers nip off all dead flower-heads as the blossom fades, but do *not* cut back into the old stem, as this will prevent flowering. At the same time any branches causing overcrowding can be removed. Annually feed with "National Growmore" at 2 oz. per sq. yd. and on poor soils mulch with any sort of manure or compost. *Prop.*—Layering in the autumn.

Tagetes (African and French Marigolds).—Half-hardy annuals of free-flowering habit and easiest culture. Best if fed generously with soot water or other nitrogenous manure during growing season. *See* **Annuals.**

Tropaeolum.—The common nasturtium and the flame flower (*T. speciosum*) belong to this genus. The former is easily grown from seed sown in May in a sunny position. The latter is a very difficult plant to grow outside the conditions which it demands. To be successful, this perennial climber must be planted in acid soil which is naturally damp and lightly shaded but yet where the new growth can reach full sun. Much disappointment often results from planting it in eastern England, for instance, after seeing it flourishing almost as a weed where the rainfall is high in Ireland and the west of Scotland.

In the genus will also be found the canary creeper, which can be used for screening purposes and will thrive in full sun or shade. Seed is sown in May in open ground and light supports supplied by way of pea sticks or strings; failure is normally due to nothing more than lack of moisture.

Tulipa (Tulip).—Thrives in a deep, rich loam, but will do well for one season in ordinary garden soil. When used for bedding, bulbs must be lifted after flowering, replanted in a trench, and thoroughly watered. Sometimes tulips may be left in the ground *if* conditions are favourable, and then the stock only needs lifting and replanting every three years. To check the incidence of tulip fire plant in late November or early December, covering the bulbs with 4–5 in. of soil and treat the ground with a fungicide like "Botrilex." Before doing so rake in a dressing of 2 oz. superphosphate and 1 oz. sulphate of potash per square yard. A small collection of wild tulips is being got together at Cambridge and grown there in the University Botanic Garden.

Viola.—This name embraces pansies, violas, and violets. Although the viola has not got the rich colours of the pansy (or its attractive markings), it has got a remarkably long season of flower, and for this reason it is invaluable as an edging plant or as ground cover for roses. *Prop.*—Both plants are easily raised from seed sown in a frame in the spring, pricked out, and then transferred to their flowering positions in late May. Alternatively, seed may be sown in July for planting out in October. Named varieties increased by cuttings in a frame in late summer.

Virginia creeper.—*See* **Parthenocissus.**

Wallflower.—*See* **Cheiranthus.**

Water Lily.—*See* **Nymphaea.**

Winter Sweet.—*See* **Chimonanthus.**

Wistaria.—One of the finest of all climbing plants for south or west walls or stout pergolas. Plants which do not flower, or only do so poorly, are probably seedlings and the true flowering habit cannot be induced; the only solution is to replace with a *grafted* plant of known flowering capacity from a reliable nurseryman. All young shoots not required for the extension of branches should be shortened to within 3 in. of the old stem in the autumn. Wistarias growing over trees do not require pruning. *Prop.*—Layer shoots of current season's growth in the autumn.

Zinnia.—Half-hardy annual, ideally grown on moist, deep loam liberally enriched with well-decayed manure. Mulch with manure after planting and apply liquid fertiliser as buds appear; plants must not suffer from lack of water. *See* Annuals.

MAKING A LAWN

In almost every garden the most prominent feature is the lawn, and often a lot of work is put into making one without any great measure of success. Usually, the reason for failure may be found in faulty preparation of the soil or premature sowing, albeit the blame is often placed on bird damage or poor seed.

For anything like a reasonable turf, the site must be thoroughly dug and the content of organic matter increased by incorporating generous quantities of materials like peat, leaf-mould, compost, sewage sludge, and animal manure. A dressing of these ingredients can be applied in a layer 3–4 in. thick and buried in the bottom of the top spit of soil. As the ground is dug to incorporate the organic matter, roots of perennial weeds should be removed.

If the site is one on which water tends to lie or if the soil is heavy, then surface drainage should be sharpened by forking into the top 2 or 3 in. a liberal application of some coarse material such as builders' rubble, road grit, screened ashes, or coarse sand. In some cases this treatment will not be sufficient, and then the installation of land drains must be resorted to. This particular task is not as difficult as is sometimes imagined, but, before a start is made, it is always a good plan to discuss the matter with an experienced man.

After the initial work a fine tilth on the soil may be obtained by thoroughly raking and cross-raking and at the same time establishing a level surface. On this point, it should be remembered that good lawns can be made on undulating ground or on natural slopes, but the things to avoid are the shallow depressions where water will naturally tend to lie. Finally, ten to fourteen days before sowing the subsequent growth of grass can be encouraged by making an application of "National Growmore" at 2 oz. per sq. yd.

Sowing is best done in the late summer at a time when the soil is moist. For the purpose, a good mixture of seed should be obtained from a reliable seedsman, and it is worth paying a reasonable price for it, as, by and large, the coarsest and roughest grasses have the largest and heaviest seeds. Opinions differ on rates of sowing, but, with care and in a well-prepared soil, 1 oz. per sq. yd. is ample; heavier rates may give quicker results, but the density of seedlings in such cases often leads to the finer grasses being choked by the coarser ones.

After sowing, the ground should be lightly raked, but not rolled. At this stage the important point is to protect the seed bed from birds by the use of hazel sticks, strings of papers tied to stakes after they have been dipped in lime-wash, and strands of black cotton. Subsequently, annual weeds may appear in quantity; these are of no consequence, and they will be eliminated once the grass is cut regularly. Until a good turf is formed —usually about twelve months after sowing—it is not desirable (or probably necessary) to use hormone weed-killers. *See* T32.

Care of Established Lawns.

Most turf is never manured from year to ye
and the soil may seriously lack plant foods.
the first place this can be corrected by making
application annually in the spring of "Natio
Growmore" at 1 oz. per sq. yd. Subsequent
if growth is below par in the early part of the ye
an application of sulphate of ammonia can
made at the same rate. To avoid scorching
blackening of the foliage, each fertiliser can
mixed with equal parts of dry soil or sand as
carrier to ensure even distribution and, what
most important, each one should be applied o
when the turf is wet and there is the prospect
rain to follow. Linked with this treatment, t
is always responsive to top dressings. A comp
for the purpose can be made up with:

2 parts of loam;
1 part of sieved compost;
1 part of fine peat or leaf soil.

This may be used in the spring at 3–5 lb. per
yd. and if the soil is heavy 1–2 parts of gritty sa
may be added.

With the introduction of new designs in mo
mowers, most lawns are seriously overcut, a
this has led to a sharp decline in the quality
the grass and the appearance of one or two p
nicious weeds. It is appreciated that special tu
such as that found on a bowling green, may
shaved off to $\frac{1}{16}$ in., but if a utility lawn is
below half to 1 in., then the quality of the gr
will deteriorate. Of course, it is a good thing
occasionally cut the grass very short, but, c
versely, if the blades of the mower are set as low
possible and left like it throughout the seas
nothing but harm can result. The reason for t
hard fact is that when the turf is cut very close
grasses simply cannot develop and spread, a
weeds will gradually establish themsel
Eventually the cultivator will be faced with
difficult problem of trying to deal with s
plants as pearlwort, yarrow, and various mos
all of which are resistant to hormones.

As for the vexed question of whether or not
remove the mowings, there is no doubt that
best turf is found where the mowings are collec
up, although in very dry weather they can be
on the surface. If the clippings are not remo
the surface of the turf tends to become choked w
semi-decayed organic matter, and conditions
brought about which are inducive to the sprea
moss.

Finally, it is worth noting that the finest tur
found on acidic—not alkaline—soils. For t
reason, lime should not be applied as a gene
rule, for apart from helping the development
coarse grasses, it encourages the growth of clo
Of course, there are times when lime is necessa
but the occasions are rare and before it is used
a good plan to test the soil by chemical means.

THE FRUIT GARDEN.

The guidance of an expert is probably m
important in the growing of fruit than for mos
the commoner vegetables and ornamentals.
is primarily because the majority of fruit t
and bushes are long-lived, and only in the cas
strawberries can a change of site or variety
made easily and inexpensively.

Gardens which are low-lying are very prone
damage from spring frosts, and should not h
too much space devoted to fruit, as returns
well prove unprofitable. Here, as with the se
tion of varieties, advice of a local expert is inva
able. Some varieties do better in certain locali
and on certain soils than others, although pers
preferences will naturally be met where possi
Varieties chosen should cover as long a seaso
is practicable so that the fruit can be used
enjoyed to the full.

Tree fruits are grown on a rootstock, and
apples and pears special dwarfing stocks m
these a possibility for the small garden.
therefore important to explain to the nursery
what type of tree is required. As a general
however, the smaller gardens will gain by
centrating on currants, gooseberries, raspber
and strawberries. Plums and cherries have

varfing stocks, and should be included only
nere sufficient room is available.
Adequate preparation of the ground is im-
rtant, and this, followed by good management,
n result in worth-while crops from most soils,
oviding they are reasonably free of frost, well-
ained, and sufficiently sunny

Apples.—Can be grown on most soils. Manure
ould not be used when planting, except in sandy
d chalky gardens. Obtain trees on dwarfing
otstocks, such as M.IX, M.VII, or MM.106.
ways stake trees on M.IX, otherwise this prac-
e is necessary only in exposed sites. The tie
ust be rigid, with a "cushion" between tree
d stake to avoid chafing, and must be renewed
nually to avoid constriction. Plant between
e October and early March, preferably before
ristmas if soil and weather allow. Make the
le large enough to spread the roots evenly;
m thoroughly while filling in and plant level
th the nursery soil mark already on the tree.
ulch around each tree with manure or compost,
ainly to avoid drying out, and supplement with
tering during the summer when necessary.
In the first year any flowers produced are best
nched out to encourage root and shoot develop-
ent. For walls or fences use oblique cordons
espaliers; these are also useful for flanking
ths and lawns. Plant cordons 2½ ft. apart
th 6 ft. between rows, and espaliers 12–15 ft.
art. For larger areas use bush trees 12–15 ft.
art.
Manuring for cropping trees should be varied
cording to growth. Generally apply 1 oz.
lphate of ammonia (or nitro chalk on acid soils)
early March, repeating this in early April if
ees are growing in grass. Give ½ oz. sulphate of
tash in February and add 3 oz. of superphos-
ate every third year. The above rates are per
uare yard, and a complete fertiliser can be used
lieu if preferred.
Young bush trees should have main shoots
duced by half in early years to produce strong
anches. Thereafter prune side shoots to three
six buds. For weak growers prune harder,
d for strong growers prune less. It is wiser to
ve a strong tree unpruned than to prune it too
verely, the latter merely encouraging even
onger growth. A few varieties (*e.g.*, 'Bram-
's Seedling,' 'Worcester Pearmain') fruit at
oot tips, and here a proportion of side shoots
ould be left unpruned. Summer pruning is
visable on restricted trees, such as cordons;
details see pears. Very few varieties are self-
tile, and at least two sorts should be planted to
sure satisfactory crops. Good combinations
'Cox's Orange Pippin' with 'Laxton's
rtune' and 'Winston' with the cooker 'Lord
rby.' Seek expert advice on pairings if in
ubt.

Apricots.—These are often an unreliable fruit to
ow, needing a well-drained, calcareous loam and
warm wall for success. Train the tree as a fan,
d once established pinch unwanted side shoots
four leaves in summer. Thin fruits when
ung, these developing mainly on spurs on older
od. 'Moor Park' and 'Hemskirk' are good
rieties.

Blackberries.—Allow plenty of room and train
ainst fences or wires. Autumn planting is
eferable, using good, well-manured soil and
tting back the cane to 9 in. from the ground.
lch with manure each spring, water freely in
ought, and cut out old canes as soon as they
ve fruited. Good varieties are 'Himalaya,'
erton Thornless,' and the parsley-leaved
ckberry. Increase by tip layering.

Cherries.—Sweet cherries are unsuited to most
dens. The trees become too large, and *must*
planted in selected pairs to fruit satisfactorily,
all varieties are self-sterile. Large wall spaces
ideal for fan trees, as the fruit can then be
tected from birds by the use of nets. Pinch
e shoots on fans to four leaves in July; further
ning details being as for plums. Expert advice
essential to ensure that suitable varieties are
wn together, the factors involved being complicated. 'Early Rivers' with Bigarreau Schrecken' and 'Merton Heart' with 'Waterloo' are good combinations.

For the small garden the dwarf-growing, acid 'Morello' cherry is more useful, being infinitely superior for preserves as well as self-fertile. It also succeeds on a north wall, but unlike sweet varieties, fruits *only* on one-year-old wood.

Currants, Black.—These are perhaps the most valuable of all hardy fruits, and bushes will give up to 10 lb. and more of currants with correct treatment. Plant from November to February, preferably autumn, at 5 ft. square on clean, heavily manured ground. Then cut all shoots to one bud above soil level. Mulch each spring with well-rotted manure and supplement with fertilisers if necessary. The mulch is essential as much for keeping the soil moist as for a general feed.

On established bushes prune preferably after fruiting or in winter, retaining strong young wood and cutting out older shoots, where possible from ground level. If necessary, alternate bushes can be cut down completely every other year to maintain vigour, as the bulk of the crop is always borne on young wood. Increase by 8-in. cuttings of one-year-old wood taken in late September from healthy bushes. Remove lower leaves and insert firmly with one bud above ground. Good varieties: 'Boskoop Giant,' 'Wellington XXX,' 'Baldwin.'

Currants, Red and White.—One or two well-grown bushes are usually sufficient for the average household. Plant between November and March at a minimum of 5 ft. square on well-manured ground and mulch each spring. Supplement with fertilisers if necessary, potash being particularly important in the form of sulphate of potash at 1 oz. per sq. yd. in February. Can be grown as cordons or fans against walls or fences, on which the pinching of young side shoots to four leaves in mid-June is essential. Winter pruning of all types simply involves cutting side shoots to one bud and tip pruning branch leaders. Propagate by 12-in. cuttings of young shoots in late September inserted to half their length with all buds removed except the top four. This enables the bush to be grown on a "leg." A permanent framework of branches is then developed, as, in contrast to the black currant, fruit is borne on spurs on the old wood. Good varieties: 'Laxton's No. 1,' 'Red Lake,' 'White Grape.'

Damson.—*See* Plums.

Figs.—A warm south wall is usually essential, 'Brown Turkey' being one of the few reliable outdoor varieties. Plant in a brick or concrete trough (with drainage holes) about 2½ ft. wide, 5 ft. long, and 2½ ft. deep so that the root run is restricted. This will curb excessive growth (which otherwise is difficult to control) and encourage fruiting. Plant in March for preference, to avoid frost injury to young shoots, and then train fan-wise. A rich soil is not essential. Figs visible as such in the autumn will never overwinter, and should be rubbed out. Those the size of a pea and less at the tips of short, well-ripened shoots, on the other hand, are the potential crop for the following year, and should be covered in severe weather to avoid frost damage. To encourage the formation of these embryo fruits pinch young shoots back to the fifth leaf in late August. Winter prune in March, removing any wood that is frosted, overcrowded, or worn out; growths should be spaced at about 1 ft. Apply a spring mulch and water freely when required to avoid premature fruit drop.

Gooseberries.—Need conditions and spacing very similar to red currants, but with rather more moisture to ensure ample new wood, as this bears fruit as well as the older wood. Apply sulphate of ammonia and sulphate of potash annually in late February at up to 1 oz. per sq. yd. of each in addition to mulching. Can also be grown as cordons, etc., as for red currants. Pruning is also similar, though not quite so severe, as the young wood is productive of fruit. Cuttings are more difficult to root, and for best results should be taken in mid-September, again as for red currants. Good varieties: 'Lancer,' 'Leveller,' 'Whinham's Industry.'

Grapes.—Outdoor vines should be grown against a warm south- or south-west-facing wall. With good cultivation, the grapes should then ripen successfully providing suitable varieties are chosen. In preparing the site ensure that it is well drained and break up the soil to a depth of about 2 ft. Add bone meal to the top few inches at 4 oz. per sq. yd. and incorporate mortar rubble, particularly on the heavier soils. Do not dig in any manure except on poor, light soils, but always apply some as a mulch after planting, repeating this every spring. On poor, hungry soils the importation of some fibrous loam is advisable where possible.

Plant in November or, failing this, before early March, with the stem about 6–9 in. away from the wall. Firm well and then wait a further two months before tying to any wires or stakes, in case of soil sinkage. Cut the vine back in winter to well-ripened wood and to just above a bud. The training of subsequent growth will then depend on the space available, single and double cordons being the most convenient. Unwanted shoots should be pinched at about 2 ft. in summer and leading shoots carefully tied in to wire or bamboo supports. The following winter (December) prune leading shoots back to well-ripened wood so as to leave 3–4 ft. of new growth. Then cut all laterals hard back to one bud. In spring reduce young side shoots to one at each bud, stop laterals at about 12 in., and pinch any sub-laterals that may develop to the first leaf. Do not allow any crop to develop, except perhaps one bunch if growth is adequate; others should be pinched off. As fruit develops, thinning should be done as required. Winter prune as before, and then in the third summer four or five bunches of grapes can be allowed if the vine is healthy, the crop then increasing annually. Shoots carrying bunches should be pinched to two leaves beyond the bunch. Winter pruning is repeated each year as already described. Sour top-soil should be carefully removed when necessary and replaced with good loam while the vine is dormant. Good varieties: 'Black Hamburgh' and 'Foster's Seedling.'

Loganberries.—A very popular hybrid berry which should be treated as for blackberries. A thornless form is now available. Suitable for a north wall.

Medlars.—A tree of spreading habit, the peculiar fruits of which are best used for jelly before they are fully ripened. Most soils are suitable, and no pruning is needed except to keep in shape.

Nectarines.—A fruit very closely allied to the peach but with a richer flavour and needing rather more warmth. The skin is smooth, as distinct from the hairiness of the peach. For full details see **Peach.**

Nuts.—The most important kinds grown are cobnuts, the closely related filberts, and walnuts, but none of these is cultivated to any great extent. The two former kinds flower very early in February, and are therefore predisposed to frost damage; similarly, the young shoots of walnuts are easily injured by spring frosts, and all are therefore inadvisable for frosty areas.

Cobnuts and filberts.—Highly developed forms of the ordinary hazel nut. The nut of a cob is only partially covered by the husk, whereas a filbert is completely enclosed by it, this being the essential difference between the two. Will grow on most soils, including the poorer ones, and spacing should be about 15 ft., choosing sites sheltered from the colder winds. Plant during the autumn. Prune established bushes in March, cutting back shoots that have borne nuts to two or three buds; strong young shoots are cut back to a catkin near their base, and the weaker ones are left untouched. In August any strong new side growths are "brutted"—that is, broken off—and left hanging until the March pruning. Gather the nuts as they fall and allow to dry. Then store
in jars for Christmas use, packing salt and coconu
fibre between each layer of nuts.

Walnuts.—Special, grafted varieties are no
available which produce early crops compare
with the unreliable seedling trees that used to b
planted. Plant between October and March an
water well in spring and summer. Do not prun
as walnuts bleed badly. Gather nuts in mid-Jul
for pickling. For storing allow to drop naturall
and remove outer husk immediately, scrubbing th
shell clean and then drying thoroughly. Th
shells can be bleached if necessary before storin
the nuts as for cobs above.

Peaches.—This fruit along with its close ally
the nectarine, is best grown against a warm sout
or south-west wall, but two varieties of peac
'Peregrine' and more particularly 'Rochester
will succeed as bushes in the open in souther
England. The fan-trained peach is one of th
most difficult trees to keep in order, as sufficie
new shoots must be retained annually to repla
old wood. This is essential, as it is only the pr
vious year's shoots which bear fruit. Badl
placed shoots are rubbed out when only an in
long, and the principle is to allow one youn
replacement shoot to develop near the base
each fruiting shoot, pruning back to the form
and tying it in as soon as all fruit has been picke
Other shoots may be used to extend the fan whe
space allows or to replace any branches or parts
them which may have become worn out. Oth
unwanted shoots are bound to arise during eac
summer, and these are either removed immed
ately or pinched to three leaves and then remove
when pruning in late summer. Those shoot
retained are spaced at about 4 in. apart.

Most peaches are self-fertile, but hand-pollina
ing on sunny days can improve the set. Excessiv
feeding should be avoided, varying this accordi
to each tree's performance, but as a general ru
a surface mulch of well-rotted manure or compo
should always be given each spring, together wit
sulphate of potash at ½ oz. per sq. yd. Pri
over and rake off top-soil and replace with go
loam every few years. Never allow the sub-s
to dry out—this can quickly occur against war
walls—and water thoroughly when doing so
ensure an even distribution of moisture. On th
other hand, drainage must be satisfactory
avoid waterlogging.

There are numerous other essential operatio
in the growing of trained peach trees (for exampl
fruit thinning), and it is impossible to deal wit
these adequately in brief notes. Would-
growers should therefore seek expert advice a
obtain literature dealing specifically with the cr
rather than risk disappointment. Good varieti
for outside wall training include: *Peache*
'Peregrine,' 'Bellegarde.' *Nectarines:* 'Ear
Rivers,' 'Lord Napier.'

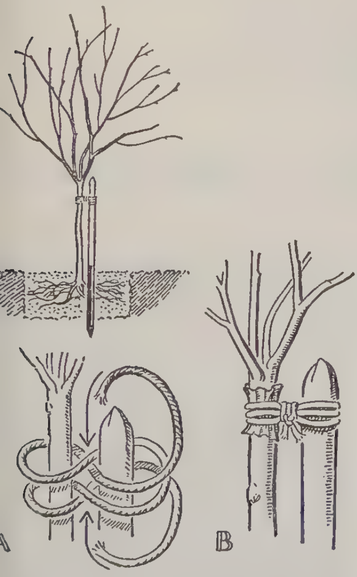
Pears.—The requirements for pears are simil
to those for apples, but the necessity for adequa
summer and autumn warmth rules out ma
varieties for northern areas. In these le
favoured localities enquire which varieites do su
ceed, and where possible make use of a war
south-facing wall. Protection from wind is ve
important, particularly from the cold easterlies
spring. Many soil types grow pears satisfactoril
providing drainage is good and the trees are look
after. Plant as for apples. Fertiliser requiremen
are also similar once cropping commences, exce
that pears may require a little more nitrogen.

Pruning (winter) is comparatively simple, t
spur pruning given for apples suiting all except
very few pears. Initial shaping is essential, c
ting the stronger shoots selected to form branch
by about half their length and keeping the cent
of the tree open. For cordons and other restrict
forms of tree, to which pears lend themselv
particularly well, summer pruning is advisab
This involves shortening all young shoots mo
than 10 in. in length to about 5 in. from the ba
Do this when the base of such shoots is hardeni
and turning brown in colour, usually late Jul
early August. Pruned shoots may then be furth
reduced in winter. Such summer treatment m
also be given to trained apple trees with advanta
during August.

Only a few pears are self-fertile and 'Co ence' is the most reliable if only one tree can planted. Good pollinating pairings include axton's Superb' with 'Doyenné du Comice' ' 'Conference' with 'Williams' Bon Chré-n.' Early varieties should be picked a little ore ripening and used quickly.

Plums.—This general term includes gages and nsons. Numerous varieties are easy to grow ; are unsuited to small gardens because of the ount of space required. Unlike apples and rs, there are no dwarfing rootstocks, and a nimum spacing of 14 ft. should be allowed for, wing the trees as half standards, or fan-trained inst a south or west wall. Flowering is during ril, and frost damage can be serious in some sons. Plant preferably in the autumn, and by ly March at the latest, using no manure unless l is distinctly poor. Young trees should be ked during their early years, and must not be owed to rub against the support.

Pruning should be reduced to a minimum, as the ores of silver leaf disease gain entry through unds such as pruning cuts and stake rubs. orten branch leaders on young trees just as ds are bursting, but on older trees prune only en branches become overcrowded. Do this ween June and August, when the risk of silver f is at a minimum. Cut cleanly and coat the unds thoroughly with a bituminous paint; at broken branches similarly immediately they noticed. Trees fruiting heavily should have branches supported and the fruit thinned in e June. Side shoots on fans must be cut to r to five leaves in late June and reduced still ther following picking if necessary. Feed pping trees regularly to encourage new growth, ng well-rotted manure or sulphate of ammonia l oz. per sq. yd. in early spring. Some varieties self-fertile including 'Victoria,' 'Oullin's lden Gage,' and 'Merryweather Damson.'



WELL-PLANTED TREE, illustrating (A) a good method of tying and (B) sapling firmly secured with sacking around the trunk and held with stout cord.

aspberries.—These are an ideal fruit for the ll garden, but because of virus disease always certified canes from a fruit nursery. Plant ween November and March on clean, well-ured ground, allowing 18 in. between canes 6 ft. between rows. After planting prune each cane back to 12 in. Do not attempt to crop them in their first year, or the production of young canes for the following year's fruit will suffer.

A semi-shaded position will answer, but full sun is preferable for quality fruit. New canes should be looped with string to a post-and-wire fence and later tied individually to each wire when fully hardened. Space them at about 4 in. and remove any weak or diseased canes at ground level. In late February cut each cane to just above the top wire, which is usually 5–6 ft. high. This removes any damaged tips and may encourage fruiting over a longer length of cane. In the second summer a fair crop should result, and netting against birds is essential. Regular watering is imperative in dry weather, and spring and summer mulches of well-rotted manure or compost should always be applied. Supplement this in March with nitrogen and potash (fertilisers) if required, this depending on how well the ground was manured before planting. After fruiting cut out all old canes and tie in the new ones as already described. 'Malling Promise' and 'Lloyd George' are good varieties.

For autumn-fruiting varieties prune all canes to the ground in late February and tie in the best during the summer for cropping in September–October. 'September' is a good variety, and 'Lloyd George' can also be used.

Strawberries.—This is the one fruit that should be included in the vegetable garden. Fresh ground can then be used regularly for establishing new beds. Plants more than two years old are seldom profitable, and the best fruit is always picked from healthy one-year-olds planted the previous August or September. Runners put in later than early October should be deblossomed the following spring, the reward being a much heavier crop in the second year. This wastes ground, however, and early planting is preferable on all counts. Prepare the ground well in advance of planting and dig in plenty of well-rotted manure or compost or both, as this is the key to success.

Because of virus diseases order certified plants from a fruit nursery and burn any unhealthy ones in old beds before planting. Insert firmly with the base of the crown of each plant just at soil level and refirm after winter frosts; space at 20 in. in rows and 2 ft. 6 in. between rows (3 ft. if possible). A mulch of rotted manure or compost is beneficial each autumn, and if this is lacking apply sulphate of potash at 1 oz. per sq. yd. instead. Bonemeal is also advisable in spring and again in July, but quick-acting *nitrogenous* fertilisers should normally be avoided.

During flowering cover the plants where possible to guard against frost damage reducing the crop. Keep the ground weed-free and remove runners regularly; a few plants should always be grown away from the main bed, deblossomed and kept purely for runner production, as this then helps to reduce the spread of virus. Ruthlessly burn any plant that remains stunted, including its runners, as this is usually a symptom of virus disease. When the young fruits are just forming spread clean straw underneath them to avoid splashing from the soil; it is a mistake to do this too early, as it increases the risk of frost damage. Net the fruit against birds and remove any rotting specimens when picking.

After fruiting remove and burn all old foliage, weeds, and straw, and feed as already described. Plant a percentage of new, vigorous runners each year on fresh ground, at the same time burning the old ones they are replacing. Good varieties include 'Royal Sovereign,' 'Cambridge Favourite,' and 'Talisman.'

Alpine strawberries require similar treatment, preferably with a semi-shaded position, and should be raised from seed. Perpetual fruiting types continue fruiting on and off well into the autumn, and should be treated as for ordinary varieties. In all cases cloches can be used from late February onwards to obtain early fruit.

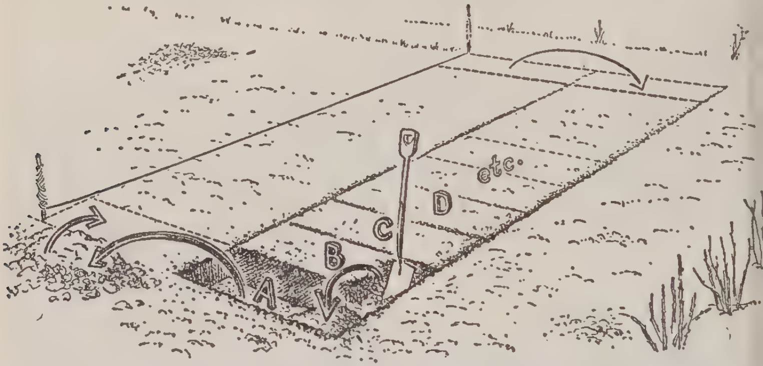
Tree Fruit Growing, by Raymond Bush, revised by E. G. Gilbert, N.D.H. (Penguin) 1962 (12*s.* 6*d.*)

The Fruit Garden Displayed (R.H.S.) Revised Ed. 1965 (7*s.* 6*d.*)

THE VEGETABLE GARDEN.

The vegetable garden is, or should be, an integral part of home economy nowadays. Home-grown vegetables, although requiring considerable labour, are cheaper and fresher than most shop supplies. The ideal site is in an open, sunny position sheltered from cold winds with the soil a deep, rich loam well supplied with humus; quite obviously very few gardens have the ideal site, and we have to do the best we can with the ground available. In laying out the vegetable plot, ease of working should be considered; the lines of vegetables should go from north to south, and paths should be wide enough for a barrow to pass. The vegetable lines should not be too long, or the soil will be trodden down too much.

Each individual will have to decide the size of his plot according to the amount and types of vegetables required, and the land available. Shelter from a hedge or wall is desirable, and a plot about 90 ft. by 30 ft. can be made to produce a succession of vegetables to feed an average family over the year. Land preparation is important; on a new site the weeds should be cut down and removed, but any turf can be left and dug in. The land should be dug two spits deep (" double digging ") in winter, and for this the plot is divided into two longitudinally and a trench 2 ft. wide and 10 in. deep is dug out at one end, as shown on the accompanying diagram. The sub-soil below the trench is then broken up and manure or compost incorporated (or turf if grassland is being dug). The next strip is then dealt with in a similar manner, and this continues down the plot until the last trench, which is then filled with the loose soil from the first trench.



DOUBLE DIGGING—A sound cultural practice. A trench 2 ft. wide and the depth of a spade is take out at A and placed as shown. The bottom of trench A is then forked up and filled in with sc from B and the process repeated with C and D, etc. In double digging the sub-soil is *always* le on the bottom and never brought to the surface.

Clay soils which are sticky are much improved by humus and constant working, but should not be dug in wet weather. Sandy soils also require plenty of humus to conserve moisture, but are less fertile, though often warmer and earlier. For the majority of vegetables a slightly acid soil is best, and a dressing of lime is only desirable if the soil is too acid. Double digging is not necessary each year, and single digging, carried out in a similar manner without breaking up the second spit, or a light forking over is sufficient for some crops, provided the ground has been well cultivated previously.

The lay-out with vegetables must be designed to provide a succession through the year and to utilise the full capacity of the ground by catch crops and a suitable succession. The land can be divided into four plots; one is used for the more or less permanent crops, such as asparagus, rhubarb, and globe artichokes, and the other three will provide a rotation. This is used to stop any group of vegetables being grown on the same land more than once in every three years, so preventing the carry-over of some pests and diseases an providing for a full use of the manures in the soi as different groups of vegetables need more c some nutrients than others. It also allows th clearance of one section to enable winter diggin and manuring to be carried out. On this freshl manured plot peas, beans, onions, leeks, and let tuces, all revelling in rich ground, should b grown. The next plot, manured for the *previo* crop, can be used for root crops—early potatoe carrots, parsnip, and beet. A light dressing c artificial fertiliser such as " National Growmore should be applied before sowing. On the thir plot the green vegetables should be grown; dressing of fertilisers is desirable, and lime shoul also be applied.

In the following season the root crops can b grown on the plot which was manured the previou year, and the brassicas grown on the land vacate by the root crops. The plot on which the brassica were growing is double dug and manured read for the peas, beans, and onions. A system of th type proves very satisfactory, but numerous vari tions can be devised, and it is really a matter f the gardener to decide his best method. Tl growing of maincrop potatoes will complicate tl system, as a large area is usually required. The are better grown separately in another part of tl vegetable garden.

Usually it is wise to have a small piece of groun available for a nursery bed. This should be good, fine soil in which seeds can be sown to supp the main plot. In all cases seed should be sow very thinly to prevent the necessity for mu pricking out, and a slug-killer is often a wi precaution to use before sowing. Sowing date as given, are mainly for growers in the South. the North sowing dates in spring will be general two weeks or more later and autumn operatio the same amount earlier. Any gardener mu adjust his work to suit local conditions of soil an climate, and this knowledge is only gained b experience of the particular area.

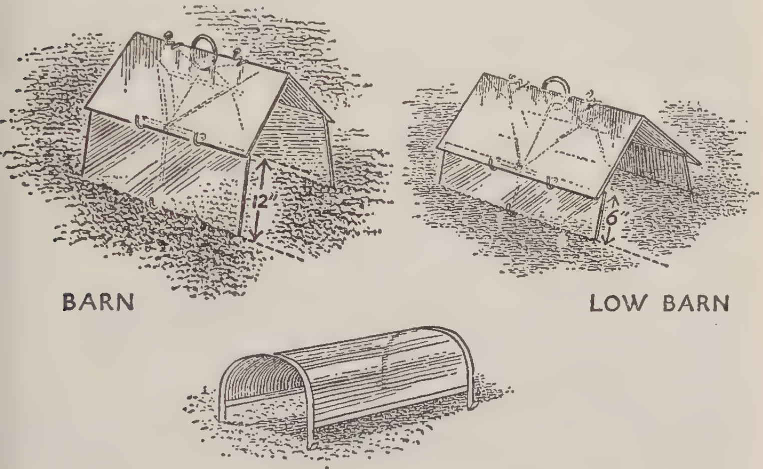
General cleanliness in the vegetable garden is all times desirable; weeds and rubbish only ha bour pests and diseases, and the hoe should b busy whenever possible. Waste material can b utilised in that essential of the modern garden- the compost heap. *See* Manures and Fertilise for description.

Frames and Cloches.—The gardener is able extend the season of many crops by protecti them under frames and cloches; this is partic larly useful where spring or early autumn fros are prevalent. The use of frames is limited, they are in a fixed position, but nevertheless th are very useful for obtaining out-of-season sala crops, especially if they are heated by electrici or a hot bed.

Cloches have the advantage of mobility and an be used on a number of crops in succession. ssentially, each is a number of pieces of glass in tent or barn shape held together by wire. Pat-ern, size, and height vary according to the crop o be covered and the manufacturer's design. A ood cloche should be of simple design, rigid and apable of standing up to ordinary winds, easily ransported, and well ventilated.

The low barn cloche is probably the most conomical type. This is 23 in. wide and 13 in. igh when erected, and will allow two rows of ttuce to be grown, with an intercrop of another egetable. The large barn or barn cloche of milar design, but with 12-in. side is 19 in. high the centre, enabling taller crops, *e.g.*, peas and warf beans, to be grown on, almost to maturity.

Dwarf varieties should be used for growing under cloches, although methods of raising the cloches another foot or so have been devised and are on the market, which allow the use of taller growing varieties. Many different vegetables can be helped to some extent in the early stages, besides those crops which can be grown entirely under cloches; the grower must decide what crops he needs and fit a rotation to cover as many crops as possible with the cloches available. This is mainly a matter of experience, but books on the subject will suggest many variations that can be tried. Intercropping with quick-maturing crops can also be practised. As instances, radish or mustard and cress can be cropped between two rows of lettuce, or a row of cos lettuce can be grown between two rows of cabbage lettuce.



BARN

LOW BARN

PLASTIC

TYPES OF CLOCHES—The most popular is the barn cloche; with 12-in. sides it will cover strawberries and peas and beans in their early stages. The low barn will accommodate three rows of lettuce in winter and cucumbers in the summer. Plastic cloches are growing in popularity, especially those patterns using toughened plastic, and have some decided advantages over glass ones.

he tomato cloche has sides 24 in. square and a sal width of 26 in. Many others of various apes and sizes are offered; the amateur should y to suit his own requirements. Other aterials have been tried instead of glass with rying success. Plastic cloches are on the arket, but their lightness entails very safe choring, and at the moment glass still seems to the best material in most instances.

Gardening under cloches obviously is a subject o large to be dealt with in a few sentences, and e reader would be well advised to refer to one of e books mentioned in the bibliography for fuller formation. A few of the main points are men-oned here and also under the individual crops.

Cloche cultivation is an intensive method of oduction, and this means that the land must be ell cultivated and manured to ensure good-ality crops at all times. About ten days before ops are sown or planted the cloches should be t in the position where they are to be used, to arm the soil. The crop is sometimes sown a onth before the normal date, and this prewarm-g ensures that the soil can be cultivated to a od tilth, as well as giving the plants a good start. atering is a problem that often bothers the nateur. Provided the soil is well watered at wing time, there should be no need to decloche water. Rain seeping under the cloches and spray directed over them occasionally will ovide enough for the crop in normal weather; dry, sandy soils it may be necessary to spray er the cloches more often. A mulch of compost also very useful to help retain water.

It must be remembered that the glass of cloches will need cleaning from time to time; the crop still needs the maximum light available, although shading of certain crops may be necessary in hot sun.

Artichokes.—Two different plants are grown as artichokes. One, the Jerusalem artichoke (*Helianthus tuberosus*), is related to the sunflower and is grown for its tuberous roots, which are second in food value only to the potato. It will grow in poor soil, but amply repays good cultivation, and may be placed at the more exposed end of the vegetable plot as a windbreak and screen. Tubers should be planted during February or March, on well-manured ground in drills 4–6 in. deep, and 2 ft. 6 in. apart, with 15 in. between the tubers. Hoe frequently during the summer and cut the stalks down in early winter. The tubers may then be lifted and stored, or better dug as required, reserving a number for replanting the following February.

The other type, the globe artichoke (*Cynara scolymus*), is often grown as an ornamental plant, but is esteemed as a vegetable for its young, fleshy flower-heads, which must be cut before the scales begin to open, after which they become hard and unpalatable. A deep, rich, well-manured soil is required, and after planting in early spring in rows 4 ft. apart, with 2 ft. between the plants, a compost or manure mulch is beneficial. A good crop may be expected for five or six years provided an annual dressing of manure is applied. After this time they should be replaced by young suckers.

planted in a fresh position. A covering of straw or bracken on the crowns is advisable during winter.

Asparagus.—This will grow on most types of soil provided that drainage is good and that plenty of organic matter is available. The site for the asparagus bed should be double dug in the autumn prior to planting, and a generous dressing of about half a barrow load of manure per square yard incorporated. Crowns up to three years old may be bought, but it is found that one-year-old crowns give the best results. Plants may be obtained cheaply by sowing seed in late March in drills 1½ in. deep and 18 in. apart and thinning the seedlings to 4 in. apart. It is thought that male plants produce more stalks of better quality than female plants, but at present no supplies of male crowns alone are available.

Planting may be on the single-row system or the wide-bed system. In the single-row system crowns are planted 18 in. apart in rows 4½ ft. apart; the wide-bed system consists of 5-ft. beds, with three rows of crowns 15 in. apart each way, and 2 ft. between each bed. Planting is best done during April and the plants are placed in a trench 8 in. deep and 1 ft. wide, with a slight ridge at the base, and covered with 3 in. of soil. The remaining soil is worked in during the summer. The roots should never be allowed to dry out.

The following March 2 oz. per sq. yd. of sulphate of ammonia should be applied; in subsequent years 3 oz. per sq. yd. of "National Growmore" applied at the same time, followed by 2 oz. per sq. yd. of sulphate of ammonia in June, after cutting, can be used. Salt, as a fertiliser, is not recommended nowadays. An annual dressing of manure or compost in November is desirable.

No cutting should be done for the first two years after planting and only a light cut taken in the third year. After this a six-to-eight-week season beginning in early May is usual. The spears should be cut when about 4 in. above soil level and severed about 2 or 3 in. below the soil, giving an overall length of 6–7 in. The fronds should be cut in October before the seeds drop, but not during the summer, as the plant is weakened. Weeds should be kept down and in the autumn the plant may be earthed up.

Varieties: 'Connover's Colossal' and 'Kidner's Pedigree.'

Beans. Three types are commonly grown, as follows:

Broad Beans are the hardiest and can, in warm gardens, be sown during autumn to obtain an early crop. Little is gained by this as a rule, and sowing in well-manured ground in February, when the soil is frost free, with successional sowings during March and April, is generally better in most gardens. The soil is broken down, finely raked, and the seed sown 9 in. apart in drills 3 in. deep, with 18 in. between each row. If double rows are sown 10 in. should be left between the rows, and 2 ft. between each pair of rows. Staking may be necessary. Plants from sowings under glass or under cloches in January may be used to obtain an earlier crop; the cloches should be removed in March and a further crop sown, and recloched.

Black aphis was a serious pest, but is now easily checked by pinching out the young tips and applying malathion or lindane as soon as any are seen. The pods may be used before the beans are fully developed and sliced as are runner beans, but normally they are picked when the beans are well formed but not tough.

Varieties: 'Aquadulce' and 'Green Masterpiece.'

Dwarf Beans (which include French, Kidney, and Haricot Beans) may be either used as young pods in a similar manner to runner beans or ripened in the pod for winter use. A rich well-manured soil gives the best results, and seeds sown during the first week in May, 2 in. deep and 6 in. apart, in drills 18 in. apart, may be followed by a second sowing at the end of May. The young plants should be thinned out to 1 ft. apart and small twigs used to stake them. If sown earlier, frost damage may occur. Seeds may also be sown in the greenhouse and the seedlings transplanted, or sown under cloches in the last week in March, provided the soil has been prewarmed.

The plants, as long as the pods are picked over frequently, will continue to bear until the frosts; a little liquid manure will be beneficial during the summer. A late sowing in July, cloched in September, will continue the season into the autumn.

If required for winter use (Haricot varieties) certain plants should be left unpicked and the pods allowed to ripen on the plants. They should not be picked green; if unripe when frosts come, the plants should be pulled up and dried in a shed.

Varieties: 'The Prince' (Cloche), 'Masterpiece,' and 'Comtesse de Chambord' (Haricot).

Runner Beans are the most popular type, and can be grown in two ways: either without stakes, in which case the tips of main and side shoots are regularly pinched out to make a bushy, dwarf plant, a method often used by farmers, or staked, with cross poles, allowing the plants to climb to the tops of the poles before pinching. Seed is sown from early May (mid-April under cloches) until late June, depending on the danger of frost, usually in a double row with drills 15 in. apart, and with seeds 3 in. deep and 6 in. apart in the rows, alternate plants being removed later.

Staking should be done as soon as the first pair of leaves unfolds, and a surface mulch is then applied. If the beans are to be dwarfed the rows should be about 18 in. or 2 ft. apart, and pinching may be required about once a week. A good, well-manured soil is essential, and plenty of moisture is required. The flowers may fail to set in dry weather, and an evening spray of water is helpful in preventing this "running off." Harvesting should be carried out regularly while the pods are young, before the seeds swell; older pods are stringy and seldom worth eating.

Varieties: 'White Czar' (white-flowered, heavy cropper) and 'Streamline.'

Beetroot.—From mid-April onwards varieties of beet may be sown on soil that has not recently been manured but is in good heart; on freshly manured soils coarse, forked roots subject to cracking occur. If in poor condition a light dressing of a complete fertiliser should be given before sowing. Sow in drills 1 in. deep and 12 in. apart and make a first thinning to 4 in. apart when the first rough leaf appears, and a second later, leaving 9 in. between the plants. Transplanting is inadvisable. Early roots for summer pulling may be obtained from a sowing of a Globe type in mid-April, and the main sowing should be made during May or early June for the winter supply. A sowing under cloches in late February will provide roots for pulling in late May.

On a heavy soil the oval-rooted types are best, but on a lighter soil the long-rooted types may be used. A sowing in late July of the Globe type will provide beet for use at the end of winter. Salad beet from early sowings may be pulled as required; the main crop should be allowed to mature and is lifted in October before the roots become woody and tough. Any damaged roots should not be stored. Twist off the tops just above the roots, shake the soil from the roots and store in boxes of sand or peat in a frost-free shed. If clamped outside, straw and a thick layer of soil should be used; if frost reaches them they are spoilt.

Varieties: globe—'Detroit Red,' 'Red Globe and 'Crimson Globe'; oval—'Cobham Early'; long—'Cheltenham Green Top.'

Sugar beet is similar but is white, not red-fleshed, and is mainly a farm crop; if desired it may be grown in a similar manner. Care should be taken in hoeing all beet crops to avoid damage to the small surface roots which feed the swollen rootstock.

Borecole.—*See* **Kale.**

Brassica.—A generic name of vegetables usually known to gardeners as "greens." This group includes brussels sprouts, cabbages, cauliflowers, kale, turnips, kohl-rabi, broccoli, and couve tronchuda. As they are all related, similar soil and cultural treatment is needed, and many pests

diseases are common to them. Each is dealt
n under a separate heading.

roccoli.—*See* Cauliflower.

russels Sprouts.—Young plants from seed
n thinly in a nursery seed bed during mid-
ch can be transplanted during May or June.
soil should be firm, well drained, in good
t, and contain adequate lime, some manure
erably having been dug in during the winter;
pplementary dressing of 2 oz. superphosphate
1 oz. of sulphate of potash per square yard is
n before planting. The young plants should
et out 3 ft. apart both ways, planted firmly,
watered in thoroughly. Regular hoeing is
essary, and about a month after planting a
e soil should be drawn round the stems.
growth seems weak a top dressing of nitro-
k should be given and this repeated in early
tember. As the lower leaves yellow, cut
n off and gather the sprouts as they mature,
ting from the bottom of the stem. Where
e is available a succession of sowings from
ch to June can be made to lengthen the crop-
period.
lub root, the worst disease of brassicas, is kept
heck by only using well-limed, well-drained
and dipping the roots in 4% calomel before
ting, and cabbage root fly, a frequent insect
, by using dieldrin.
arieties: early—'Cambridge No. 1'; mid-
on—'Rous Lench' and 'Triumph' (dark
ge, distinct).

abbage.—Sowings in March and April for sum-
use, in May or June for winter use, and in
July or August for spring use will give a suc-
ion of cabbages all the year round. Seed is
n thinly in a nursery bed of well-firmed, limed
clear of weeds, in drills ¾ in. deep and 6 in.
t, and the seedlings are dusted with D.D.T.
heck flea beetle attack (prevalent with all
sica seedlings). All cabbages are gross feeders,
a well-drained soil in good heart, with
uate lime, is required.
Spring cabbage" should be sown during late
(north) and August (south). If sown too
the plants may "bolt" without making a
t. The young plants are set out in mid-
ember 18 in. apart and with 18 in. between
rows if for hearting, or 9 in. apart with 18 in.
veen the rows, in which case the alternate
ts are cut for "spring greens." On a heavy
ridging along the rows of plants keeps the soil
d the roots drained and helps to prevent
ening by frosts. In cold districts cloches may
sed with advantage to help plants through the
er. In early March a dressing of 1 oz. per
yd. of sulphate of ammonia or nitro-chalk is
od stimulant.
eed of "summer" and "autumn cabbage"
wn in March and April and planted during
May and June, 18 in. to 2 ft. each way be-
n the plants, depending on the variety. The
ts should be thoroughly watered, both before
after transplanting. A top dressing of 1 oz.
sq. yd. nitro-chalk may be given if required.
Winter cabbage," maturing from October to
uary from sowings during May and early
, are set out 2 ft. apart each way in July or
August, usually on ground which has been
ped with early potatoes or peas. No nitrogen
liser should be given late in the season, as
growth, liable to frost damage, is encouraged.
alanced fertiliser, such as "National Grow-
e," may be used if needed. When the stalks
bbage are left standing over winter a common
tice is to cut across the tops to obtain bunches
aves, for use as greens during early spring.
Savoy cabbages" mature during winter and
spring from seed sown in May. Seedlings
transplanted in late July and early August
land manured for the previous crop, to which
essing of 2 oz. superphosphate and 1 oz. sul-
e of potash per square yard has been given.
young plants should be set out 2 ft. apart
way; they are exceptionally hardy, and
ld be grown in every garden in case of a hard
er.
arieties: Spring sowing—autumn cutting,
hound' (early), 'Winningstadt.' Autumn sowing—spring cutting, 'April,' 'Wheeler's Imperial.' Savoy 'Ormskirk Late Green.'

Red Cabbage is slow to mature; plants from sowings in August are transplanted 6 in. each way in autumn and set out in early spring 18 in. each way. They are ready to cut in late summer.

Cardoon (Cynara cardunculus).—Closely related to the globe artichoke and grown for the blanched hearts. Seed is sown in trenches 18 in. wide and 1 ft. deep; 3 in. of manure is worked into the bottom soil and covered with 3 in. of fine soil. Three or four seeds are dibbled in every 18 in. and covered with a flower pot till visible, and then thinned out, leaving one strong seedling at each station. Protection from sun and late frosts is provided by twigs over the trench, and copious watering is given during the summer. On a fine day in September the plants are blanched by tieing the leaves together and covering with dry hay, 3 in. thick, kept in position by raffia, and earthed up in the same way as celery. Blanching is completed in about a month. Litter over the top protects them from frost.

Carrots.—A light, well-drained soil, enriched with decayed organic matter, is suitable for carrots. No fresh manure should be given, but a light dressing of "National Growmore" fertiliser can be applied prior to sowing. The surface is left rough until sowing time and then broken down to a fine tilth. The first sowing is made in early April in drills ¾ in. deep and 12 in. apart, and a succession is obtained by sowing at intervals of a month until the end of July.

On heavy, unfavourable soils stump-rooted varieties are best grown, long-rooted varieties needing a light soil. Thin out the stump-rooted varieties to 4 in. apart and the longer varieties to 6 in. Thinnings should be removed and the soil pressed firmly back to minimise damage by carrot fly. The early sowings are pulled as required, but the later sowings for winter use should be lifted in October and stored in slightly damp sand in a frost-proof shed or clamped in the open.

Frames and cloches are sometimes used to obtain early and late carrots. Seed of a quick-growing variety, such as 'Amsterdam Forcing' or 'Early Nantes,' sown in late January under cloches or in frames will provide an early crop; the same varieties sown in frames or cloches in early August will provide young carrots for the autumn. Carrot fly is a bad pest, especially on light soils; the seedlings should be dusted with lindane or dieldrin when 2–4 in. high to prevent the flies from egg laying.

Varieties: globular—'Early Gem'; stump-rooted—'French Short Horn'; intermediate—'Amsterdam Forcing' and 'Early Nantes'; long—'St. Valery' and 'Long Red Surrey.'

Catch Crops.—A term used for quick-growing crops interplanted between rows of other crops. Radishes between rows of broad beans, and lettuce between celery rows provide examples. In this way the best use of a limited amount of land can be made.

Cauliflower.—Broccoli is for all practical purposes a hardy winter cauliflower. Seed is sown ¾ in. deep in a nursery bed from mid-April to mid-May, depending on the variety, and transplanted during June and July on to firm soil, well manured for the previous crop. The plants are set out 2 ft. apart each way; 2 oz. superphosphate and ¾ oz. of sulphate of potash per square yard may be hoed in before transplanting. No nitrogenous manure should be given late in the year.

Varieties: cauliflower—'Snowball' (summer), 'Majestic' (autumn). Broccoli—'Snow's Winter White' (winter), 'St. George' (early spring). Sprouting broccoli—'Nine Star Perennial' (a many-headed sort).

Sprouting broccoli is very hardy, has a more leafy head, and is cultivated in the same way. Purple- and green-sprouting varieties are grown.

Summer cauliflowers require a soil which has been limed and manured during the winter; 1–2 oz. per sq. yd. of superphosphate should be given before transplanting. An early sowing in frames in February or March will provide plants for cropping in June. These should be hardened off and planted in March or April from 18 to 24 in. square, depending on the variety. Seed sown outdoors in April in drills ¾ in. deep will give plants for transplanting in May or June, for cropping from late July onwards. If growth is slow a dressing of 1 oz. per sq. yd. of sulphate of ammonia should be given. Leaves broken over the curds will help to prevent any damage from early frosts. Varieties given in previous paragraph.

Celeriac.—A plant allied to celery grown for its edible root, which resembles a turnip but has the flavour of celery; the stems are bitter to the taste and are not eaten. It is used in salads or boiled as other root crops. Seed is sown in gentle heat in March and seedlings pricked out into seed-boxes, 2 in. apart each way. In June, after hardening off, the seedlings are planted out in shallow drills 18 in. apart, leaving 12 in. between each plant in the row. Water freely during the summer and remove side shoots as they appear. Lift the roots in October or November and store in a frost-free shed.

Celery.—Richly prepared ground is required. A trench 15 in. wide and 1 ft. deep is taken out and manure worked into the bottom of the trench. The soil is then returned to within 3 in. of the ground level. Seed should be sown in early March at about 60° Fahrenheit and the seedlings pricked out in deep boxes 3 in. each way and gradually hardened off. Celery seed is very fine, and care should be taken to cover it with only a fine layer of soil; if covered too deeply it may not germinate.

In late May or June set the plants out in staggered double rows 1 ft. apart, with 10 in. between the plants, and water them in. Frequent watering during the summer is required, and a light dressing of nitrate of soda will stimulate them if growth is poor. Before earthing up to blanch the plants, tie the stems loosely below the leaves and remove any suckers. Earthing up begins when the plants are about 15 in. high; the ground should be moist, and the first earthing should only be slight. The second and third earthings, at intervals of about three weeks, should be more generous, but should never reach higher than the base of the leaves, and no earth should fall into the heart. For exhibition purposes brown-paper collars may be tied round the stalks before earthing. The final earthing should cover all the stems right up to the leaves, and the soil should slope away neatly. In winter litter or bracken spread over the plants will help protect them from frost.

Celery fly is a serious pest, and the brown leaf-blisters should be pinched to kill the maggot inside and lindane applied two or three times at fortnightly intervals. Slugs should be discouraged with a good slug killer. Leaf spot, a seed-borne disease, can be prevented by spraying with Bordeaux mixture.

Varieties: white—'Solid White'; pink—'Clayworth Prize Pink'; red—'Standard Bearer' self-blanching—'Golden Self-Blanching.'

Chervil.—An annual herb sown during March in drills 10 in. apart, and thinned to 6 in. in the rows. Further sowings can be made during the summer. Used in salads and soups.

Chicory.—The young, blanched growths are used in winter salads. Seeds are sown in drills 1 ft. apart in May; the young seedlings are thinned to 8 in. apart and grown on until October or November, when they are lifted and the roots trimmed to 8 or 10 in. long. They are then planted in deep boxes in a moist, sandy soil 5 in. apart each way, leaving 1 in. above the soil surface, and the boxes put in a warm greenhouse or cellar. No light must reach the crowns; one method sometimes used is to cover the crowns with 6 in. of sand. When the blanched growths show through they are about 6 in. high and ready for cutting.

Chives.—These are like small onions, and the leaves are used for flavouring salads and soups.
They are easily grown in window boxes and to
gardens. Bulbs can be planted in March 6
apart and divided when the clusters become t
large.

Corn Salad or Lamb's Lettuce.—Occasiona
grown for the leaves, which are used in ea
spring salads. Seed sown from August to Octob
will provide plants for winter and spring use.

Couve Tronchuda.—A large brassica known
"Portugal cabbage," not generally suitable
smaller gardens. Seed is sown in March and t
plants set out 2–3 ft. apart each way. The hea
may be cooked in the same way as cabbage.

Cress.—An annual growing rapidly from se
and used as a salad when only the seed lea
have developed. Seed sown as required, in bo
of light, moist soil and covered with brown pa
until germination, when it is removed, will prov
salad all the year round. The seed is mer
pressed into the soil and the boxes kept moi
Cress may even be grown on damp flannel in
window.

Cucumber.—The cucumber of the shops
grown as a specialist crop under glass. Tempe
tures of 85° Fahrenheit or more may be requir
and only occasionally are they grown by the an
teur, although cloche and frame culture is n
popular.

Ridge cucumbers, which are smaller and pric
outside, may be grown outdoors in summ
Plants from seed sown singly in pots un
glass can be planted during late May on ridges
good, well-manured soil or, alternatively, sown
the ridges 1 in. deep at the same date. Wa
freely during the summer and cut the cucumb
while young to encourage further production.

If cloches are available greenhouse-raised
cumbers can be planted under them, in mid-Ap
Frame cucumbers are less hardy, but young pla
raised under glass can be planted under cloches
early May.

Varieties: ridge—'King of the Ridge' a
'Stockwood Ridge'; frame—'Conqueror' a
'Telegraph.'

Endive.—Used in winter or autumn sala
Seed is sown during April in drills 18 in. ap
and the seedlings thinned to 12–15 in. apa
Sowings in June and August will provide a s
cession. A rich soil and plenty of moisture
the main requirements; before eating blanch
is necessary, as the leaves are very bitter. Thi
achieved by tieing the leaves loosely together a
covering the plants with inverted flower p
(with the holes blocked) to exclude the lig
frost should be kept out by piling litter over
pots in winter. If cloches are used they can
coated inside with lime-wash to achieve the sa
effect. Alternatively, plants may be lifted
October and blanched in darkened frames.

Varieties: summer—'Green Curled'; winte
'Batavian Broad Leaved.'

Fennel.—A perennial culinary herb used in
sauces and salads. Blanched stems may also
cooked in the same way as celery. Seed is sow
drills 2 ft. apart in rich soil and the seedli
thinned to 18 in.

French Beans.—*See* **Dwarf Beans.**

Garlic.—One or two "cloves" planted
February, 9 in. apart, will provide ample ga
for salads, as only a little is required. A
growth is complete in summer the bulbs can
lifted, dried, and stored and some saved for
planting.

Haricot Beans.—*See* **Dwarf Beans.**

Herbs.—Many herbs are useful in small qua
ties for flavouring and garnishing, as well as be
decorative. If possible, a separate herb gar
should be made as a feature in the garden, or t

y be used as edging plants. Perennial herbs, which borage, caraway, chamomile, chives, nel, garlic, horseradish, lavender, mint, penny- al, marjoram, rosemary, rue, sage, tansy, ragon, and thymes are the main types grown, uld be given a permanent position. Those wn as annuals—anise, basil, coriander, dill, sley, purslane, and summer savory—can be d as "fill-ins" on the vegetable garden. ck and cobble paths associate well with herbs, parting something of the character of the gar- s of bygone days, when herb gardens were sidered one of the most important features.

orseradish.—A deep-rooting perennial herb ich appreciates a well-manured, moist soil. s easily propagated from root cuttings and can ome a nuisance, as pieces of root left in the soil l make a new plant; care should be taken to the complete root when digging it for use. aight roots planted in spring with the crowns n. below soil level and 1 ft. apart can be lifted use in autumn; no further treatment is uired, apart from keeping weeds in check. ne of the roots should be kept for planting the owing spring.

ale.—Very useful during a cold winter, when er green vegetables are scarce, because of its diness. Seed sown in April or May will pro- e young plants for transplanting 18 in. apart h way in July or early August, on to a site d for peas or early potatoes, in good heart. A ch crop of lettuce can usually be taken from ween the rows. The variety 'Hungry Gap' sually sown in rows 18 in. apart where it is to ture and thinned, leaving 18 in. between the nts. There are many varieties; which types grown is a matter of personal preference.
arieties: 'Cottager's' and 'Hungry Gap.'

idney Beans.—*See* **Dwarf Beans.**

ohl Rabi.—A brassica with a swollen stem e, in flavour and appearance something be- en a turnip and a cabbage. Seeds sown in il in rows 1 ft. apart are thinned to 1 ft. apart he rows, and the swollen stem harvested when ut the size of a tennis ball. If left to grow it omes coarse.

amb's Lettuce.—*See* **Corn Salad.**

eeks.—A vegetable which repays planting on ell-manured soil. If they are to follow winter ens, then manure or compost should be dug fter the previous crop is cleared. Leeks may sown from early March to April in lines 8 in. rt on a prepared seed bed, and the seedlings nsplanted as land becomes available during e and July, when about 6 in. high. Thinning he seed bed should be unnecessary provided sowing has been correct. The seedlings are out 9 in. apart in rows 15 in. apart; a hole is le with a dibber, and each seedling dropped in watered thoroughly. No firming is needed, watering should tighten the plants sufficiently. ernatively, drills 4 in. deep and 15 in. apart be drawn out with a hoe and the plants put in. apart in the drills.
egular hoeing is required, and a feed of sul- te of ammonia (1 oz. per gallon of water) can applied if in poor growth. In September a e earth should be drawn up around the roots, ch should, by then, be almost full grown. ks are very hardy and can be left in the soil il required for use.
arieties: 'Lyon' and 'Musselburgh.'

ettuce.—Two main types are grown: cos let- e, a summer crop with long, straight leaves t curl inwards naturally or are tied in so that heart is more or less blanched; and cabbage uce, which are broad and spreading, with nd cabbage-like hearts, and are grown to sup- salad all the year round. Lettuce should be wn on ground manured during autumn or ter, dug and left rough till planting time, en it is broken down and raked to a fine tilth. Seed, sown in January in frames and cloches, or outdoors in March and at fortnightly intervals thereafter, a little at a time, until September outdoors, or October in frames and cloches will provide lettuce for most of the year. Sow thinly in drills ½ in. deep, in rows 1 ft. apart, and thin out or transplant young seedlings so that they are 9–12 in. apart, depending on the variety. Quick, unchecked growth with adequate moisture is required; a dressing of bonemeal worked into the soil before planting and a light dressing of sulphate of ammonia in water on poor soils will help growth considerably. Aphids may be troublesome, and should be checked by using lindane or malathion.
Varieties: summer—'All the Year Round' and 'Continuity'; early spring—'Arctic King' and 'Cobham Green.'

Maize.—*See* **Sweet Corn.**

Marrows.—Pumpkins, gourds, bush, and trailing marrows all require similar treatment; plenty of sun and water and a rich soil, such as an old hotbed or compost heap, which will provide a porous medium of humus. Seed can be sown singly in pots under glass in March, or outdoors on the site in May. For cloches a bush variety must be used, and greenhouse-raised plants are cloched in mid-April. Plant four or five seeds in groups about 6 in. apart and 1 in. deep and finally thin to two plants 15 in. apart. Protection from late frosts may be necessary. Water copiously and hoe regularly. Cut marrows when about 12 in. long to encourage further fruits. Some can be left until they are full size and cut before the frosts, for storing in a dry, frost-proof place.
Varieties: bush—'Green Bush' and 'White Bush'; trailing—'Long Green Trailing.'

Melons.—Although usually a glasshouse crop, melons can be grown outdoors under cloches and in frames. Seed is sown under glass in April at 60° Fahrenheit, and seedlings can be set out 3 ft. apart in early May. The soil should be manured generously and the seedlings planted on a mound of compost mixed with soil. The plants must be stopped at the fourth or fifth leaf to encourage laterals. Two can be selected to grow on and, when 18 in. long, pinched out to obtain sub-laterals, which will bear the fruit. The female flowers may require pollinating, and on a sunny day a male flower or rabbit's tail can be used to transfer the pollen; as soon as the young fruits swell, remove all but two or three per plant and pinch back the laterals bearing fruit to two leaves from the melon. A feed of dried blood once a week, with plenty of watering (though not saturation!) will help the developing fruits. Light shading may be necessary.
Varieties: 'Dutch Net' and 'Tiger.'

Mint.—Easily grown from suckers in any soil. For winter use a few pieces can be planted in a frame. A number of varieties—'Apple Mint,' 'Peppermint,' and 'Spearmint'—can be grown besides common mint.

Mushrooms.—Growing mushrooms is really a specialist occupation. For the experimental amateur, beds of composted stable-manure are made up in a warm, damp cellar or disused air-raid shelter. Pieces of spawn are inserted when the temperature of the compost has dropped to about 70° Fahrenheit and the whole bed covered with an inch of inert sub-soil. The air temperature should be from 60° to 70° Fahrenheit, and in a few weeks mushrooms may appear. Full instructions will be given with the spawn, but it is advisable to consult a text-book dealing with the culture, as even for professional growers a crop is never certain.

Mustard.—Grown exactly in the same way as cress, but is ready two or three days earlier. If used together, mustard seed should be sown two or three days after cress. Again it is the seed leaves which are eaten.

Onions.—These respond well to good cultivation. The site is dug deeply in winter, manure incorporated, and left rough until February, when it is broken down to a fine tilth and firmed well. Seed can be sown ¾ in. deep in drills during August and planted in March for exhibition onions, but the usual practice is to sow seed in late February outdoors or under glass in January and transplant during April in rows 12 in. apart with 6 in. between the onions, taking care to keep the bases about ½ in. below the surface. If sown outdoors and thinned the thinnings may be used in salads. Autumn-sown onions are liable to bolt, but less liable to attack by onion fly than spring-sown plants.

Dressings of sulphate of ammonia or nitrate of potash may be given during the growing season, but not later than July. In August the tops are bent over to hasten ripening and the bulbs harvested in a dry spell at the end of the month, first laying them on the ground for a day or two to dry off. They should be stored in a dry, airy place. The chief pest is onion fly, controlled by dusting the seedlings with aldrin at the loop stage. Onion sets are small onions produced the previous summer, stored and replanted in spring to obtain very large bulbs. They are particularly valuable on poor soils.

Varieties: spring sowing—'Bedfordshire Champion,' 'Best of All,' and 'White Silverskin' (pickling); autumn sowing—'Giant Zittau,' 'Sutton's Solidity,' and 'White Lisbon' (salad onions); sets—'Ebenezer' and 'Stuttgarter Reisen.'

Parsley.—Sow thinly in rows 8 in. apart during March and again in July for a succession of young foliage; thin to 4 in. between plants.

Parsnip.—Grow parsnips on ground manured for a previous crop; if given fresh manure splitting and forked roots occur. Dig the soil deeply, and at sowing time in March, work the soil to a fine tilth. On a soil unsuitable for deep-rooted crops special holes 10–12 in. apart, filled with sifted soil, may be prepared. If this method has to be used four or five seeds are sown per hole; normally drills 15 in. apart and 1 in. deep are made and four or five seeds sown every 9 in. The seedlings are thinned, leaving one at each station. Parsnips should be left in the ground until needed; litter over the rows will ease lifting in frosty weather.

Varieties: 'Evesham' and 'Student.'

Peas.—Dig the ground well in autumn and add a generous amount of manure or compost. Seed sowing begins at the end of February, and can be continued at three-weekly intervals until early July. Under cloches sowings in January and October will lengthen the season. Both early and late sowings should be of a quick-maturing variety. Seed is sown in drills 6–8 in. wide and 3 in. deep, with 2 ft. between drills; the seeds can be scattered thinly in the drill or spaced 3 in. apart in a treble row. Cover with 2 or 3 in. of soil and as soon as the peas are about 2 in. high stake with twigs.

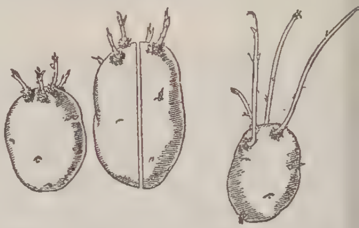
Failures are often due to attacks by birds and field-mice. The former should be discouraged by netting and the latter by trapping. Pea-sticks will be necessary for the taller varieties which should have 3–4 ft. between the rows. With limited space only the dwarf quick-maturing varieties should be used. A summer mulch will keep the soil moist, and picking should be done regularly.

Varieties: 1½–2 ft.—'Kelvedon Wonder,' 'Kelvedon Triumph,' and 'Meteor' (cloches); 2½ ft.—'Onward'; 3½–4 ft.—'Gladstone.'

Potatoes.—In general, it is only economic for the amateur to produce an early crop; the main winter supply can be grown if room and labour are available. They should be grown on land well manured the previous season, dressed at planting time with a mixed fertiliser, such as "National Growmore," at a rate of 1½ lb. to a 30-yd. row. The soil should not contain too much lime, as the damage of scab disease is increased.

"Seed" tubers about the size of a large egg are best used, and these can be bought or saved from the previous season's crop. Large potatoes may be cut leaving about three eyes to each part. Ne stocks should be bought occasionally if the "seed is home saved to obviate risk of virus. "Seed should be put in trays during February in a fros proof shed to sprout, and in early April th "first-earlies" can be planted.

Drills 2 ft. apart and 4–5 in. deep are taken ou and the sprouting "seed" planted 12 in. apart the rows. Maincrop varieties are planted in ear May 15 in. apart. The young growths should protected from frost by earthing up slightly, ar a further earthing is done as the potatoes matur This practice of earthing prevents the tubers ne the surface from becoming green when exposed light, keeps weeds down, and protects the tube from spores of potato blight, which are washe into the gullies. If growth is poor sulphate ammonia can be applied at a rate of ½ lb. per 3 yd. row. Early varieties should mature in la July and later varieties in September and Octobe when the tops (haulm) turn yellow the crop ca be lifted, dried for a few hours (too much ligh will turn them green), and stored in boxes in frost-proof shed or clamps.



Seed Potatoes—Good seed is essential f first-rate crops. Illustration shows (*left*) well-sprouted tuber, (*centre*) a large we sprouted tuber suitable for cutting, a (*right*) a poor, badly sprouted tuber.

Potato blight is a common disease, and contr by spraying with "Bouisol" before the leav touch in the rows is effective. Virus disease spread by greenfly, are checked by using "seed from Scotland, where greenfly is less troubleson because of the lower temperatures. Colora beetle should be watched for, and if found notifi to the Ministry of Agriculture.

Varieties: Discerning growers will find the f lowing well worth growing: 'Edzell Blue' (viole coloured skin; excellent cooker), 'Pentland Del (white-fleshed; heavy cropper), 'Red Crai Royal' (red-fleshed; heavy cropper), 'Ulst Chieftain' (white-fleshed, good early variet Epicureans seeking a first-class potato should gro 'Maris Peer', a sort understandably gaining popularity in Scotland, since its introducti Another interesting sort is the Dutch-rais 'Record', a yellow-fleshed variety which has trace of sweetness in its flavour.

Pumpkin.—*See* Melon.

Radish.—Most cultivated ground is suitable f growing radishes; successional sowings at fo nightly intervals from early March until May drills ½ in. deep should be made. Summer-so radishes bolt and are hot and tough, but autu sowings for late salads can be made. As radish germinate very quickly, they can be sown togeth with another crop and used quickly, and a enable the rows to be seen and hoed early.

Varieties: 'French Breakfast' and 'Scar Globe.'

Rhubarb.—Before planting the ground shou be generously manured and deeply dug. Crow are planted in March, 3–4 ft. apart each way a mulched, but no rhubarb should be pulled u the following year, when a light pull can be tak Remove any flowering shoots and give a dress of sulphate of ammonia if growth is we Manure well each winter; if early supplies needed, some of the crowns can be covered w inverted boxes or barrels and a packing of lo straw or bracken. An established, well-cultivat bed will continue almost indefinitely.

Sage.—A hardy shrub for the herb garden easily sed from cuttings. The leaves are harvested l dried in summer.

Salsify (Oyster Plant).—A winter root rather e a parsnip which requires similar growing nditions.

avoy.—*See* Cabbage.

Scorzonera.—A winter root cultivated in the ne way as salsify. It has a purplish root instead he yellow-green one of salsify.

Sea-kale.—A perennial plant native to our sea-res, which can be either grown from seed sown March and left for two years to produce forcing wns or from bought thongs, which are planted ing March, 9 in. apart in groups of three, ving 3 ft. between groups. During summer a nure mulch and nitrogenous fertiliser can be plied. When the tops die down in autumn the wns are covered with boxes to force and blanch new growths. Crowns can be covered in cession to keep a supply. Earlier sea-kale can obtained by lifting crowns in November. ese are planted in batches five or six to a pot, ered well, and a second pot, with the hole cked, placed over them. In a warm green-se or similar position they should develop iciently for cutting in about three weeks. gs are the chief pest outside, and should be kept heck by a proprietary slug-killer.

hallots.—A popular crop for the small garden. llots are purchased as bulbs, like small onions. deep, well-manured soil is required, as for ons, and they are planted during February, bulbs being pressed about half their length soft soil, 6 in. apart in the rows, leaving 1 ft. ween rows. In mid-July the little bunches of bs can be lifted. Leave them on the surface to for a few days and then store in a dry, frost-of shed. Some, about the size of a shilling, uld be kept for planting the following year.

pinach.—Sowings in February to April on a -manured soil will provide a succession during summer. Sow in drills 1 in. deep and 12 in. rt and thin the young plants to 3 in., and then in., using the second thinning to eat. A ing of the prickly variety in August at the e distances will provide a winter crop. When ing gather a few leaves from each plant in the .

arieties: 'America' and 'Giant Prickly.'

prouting Broccoli.—*See* Cauliflower.

ugar Beet.—*See* Beetroot.

wede.—*See* Turnip.

weet Corn (Maize).—Gardeners should distin-h between the types of maize used for poultry and those which supply sweet corn for an consumption. It is wise to use cloches for ving sweet corn, as it is only half-hardy and nts transplanting. Seeds sown under cloches id-April in two drills 12 in. apart and 1½ in. should be placed 1 ft. apart in staggered tions in the rows. More robust varieties may 15 in. from plant to plant. A soil well ured for the previous crop is best used, and a ch can be given as soon as the plants are a few es high. The first cobs should be ready by July, and should be eaten when the cob is y.

ariety recommended: 'John Innes Hybrid.'

rragon.—A herb used for flavouring vinegar. ed by root division in spring. Cut down and l for use in winter.

mato.—A sunny, sheltered site is required, rwise ripening outdoors in our climate is un-in. Sow seeds under glass in late March and harden off the plants in a cold frame or buy plants for setting out in late May or early June. The soil should be thoroughly dug and some artificial manure applied before planting. Allow 18 in. between plants and 2½ ft. between rows, and put in a strong stake with each plant. Keep to a single stem, pinching out side shoots regularly. When four or five trusses are set pinch out the top of the main shoot.

Feed with a liquid manure during summer. Fruit which fails to ripen outdoors can be gathered and stored at about 50° Fahrenheit or the plants laid flat on the ground and covered with cloches, when the tomatoes should ripen. Under cloches plants can be planted out in mid-April instead of late May, gaining six weeks growing time, and the Cloches removed when they become too large.

Potato blight attacks tomatoes, and a spray of "Bouisol" during the first week in August and repeated after fourteen days will give a control.

Varieties: 'Market King' and 'Moneymaker'; some heavy-cropping sorts have little or no flavour and a thick skin.

Turnips.—Ground manured the previous season should be dug well and dressed with 2 oz. superphosphate per square yard. An early variety can be sown during April in drills ¾ in. deep and 15 in. apart, followed by successional sowings at three-week intervals as required. The main crop for storage is sown in July and August, and seedlings should be thinned gradually to 10 in. apart. Use when about the size of tennis balls. A sowing can be made in September, left almost unthinned and the tops used as "greens" in spring. In autumn the storage crop is lifted and all undamaged roots put in sand in a shed or clamped. Flea beetle and turnip fly can be checked by D.D.T. at the seedling stage.

Swedes are grown in a similar manner.

Varieties: turnips—'Early Milan' (summer) and 'Green Top Stone' (winter storage); swedes—'Purple Top.'

FERTILISERS AND ORGANIC MANURES.

The elements essential for healthy plant growth may be roughly grouped into classes—first, those required in some quantity, the major elements, nitrogen, potassium, and phosphorus; secondly, calcium, magnesium, and sulphur, which are required in lesser quantities; and thirdly, the trace elements, boron, manganese, iron, zinc, copper, and molybdenum, of which only minute quantities are needed. As well as the elements mentioned, others, such as silicon, aluminium, chlorine, nickel, and sodium, are often found on plant analysis, but the evidence that these are essential is inconclusive, though they may be beneficial to certain crops.

It is important to remember, when adding fertilisers to the soil, that different crops may require relatively more of one element than another, but a balance between all the elements is essential. As an instance, brassicas (the cabbage family) are gross nitrogen feeders, while root crops (*e.g.*, carrots) require far less nitrogen, and an excess may be harmful. A further point to notice is that although an element may be present in the soil the plant may be unable to absorb any because it is being kept in an insoluble state by excess of another element. An instance of this is the frequent yellow and sickly appearance of plants on very chalky soils due to lack of iron, which is present, but locked in an insoluble state by too much calcium.

The elements needed by the plant are in the form of various compounds, such as nitrates and phosphates, and may be applied as artificial fertilisers, which are manufactured, or as humus, which contains most of the foods required and also provides the essential soil micro-organisms or bacteria, without which the soil would be inert and no plants would grow. Bacteria break down the complicated animal and vegetable matter of which humus is composed to soluble compounds which plants can absorb. Humus can be supplied as farmyard and poultry manure, leaf mould, compost, sewage sludge, spent hops, and from animal by-products like hoof and horn, dried blood, meat and bone meal, and many others.

Nitrogen is mainly concerned with vegetative growth, encouraging leaf and stem formation. It is also contained in chlorophyll, the green colouring matter of the plant, and one of the symptoms of nitrogen starvation is a pale-green colour to the leaf, indicating a lack of chlorophyll. Most of the nitrogen compounds used are soluble, and it is a wise maxim to apply "little and often"; if given in large doses much is washed through the soil and wasted.

Nitrogenous fertiliser should not be given to any plant late in the season, as sappy growth, easily damaged by winter cold and frosts, is encouraged. Similarly, at no time should large quantities be given to any plant, as this results in an excess of leafy growth, which is very susceptible to disease and adverse conditions of drought and cold; also plants tend to be later flowering.

Sulphate of ammonia is the most used inorganic nitrogenous fertiliser, and is excellent for spring use on seed beds, lawns, and early crops, and it is contained in most fertiliser mixtures. It makes soils acid in reaction, and if both lime and nitrogen are required, nitro-chalk should be used instead. Other nitrogen fertilisers used are potassium nitrate, which has the advantage of supplying two major elements at once, and is very soluble, and nitrate of soda, often used on beet and mangolds. The latter chemical should not be applied in excess, as too much sodium has a bad effect on soil structure. These inorganic fertilisers are all soluble and quick acting. As a general guide, 1 oz. of the fertiliser to a gallon of water, applied at 1 oz. to a square yard, is a good general summer dressing, given at intervals of two or three weeks. It should always be given after rain or watering, and should be applied to the soil and not to the foliage.

Among organic fertilisers containing a percentage of easily available nitrogen are dried blood, soot, and meat and fish meals. Slower to decompose, and so having a more lasting effect, are shoddy (wool waste) and hoof and horn.

Phosphorus is concerned in the plant with the production of young cells of the root and shoot, and also encourages flower and fruit production and early ripening. Most of the compounds are relatively insoluble (rendering absorption by the plant difficult), and so large amounts can be supplied without deleterious effects, especially on acid soils, where the availability is less than on alkaline soils.

Phosphorus is generally applied to the soil in the form of phosphates, and among these superphosphate of lime is quick acting, and is usually applied at 2–3 oz. per sq. yd. in spring and summer, when the need is greatest. More slow acting is basic slag, a by-product of the steel industry, sold as a fine black powder and containing, besides phosphates, many of the trace elements, as well as a considerable percentage of lime. This is good for application to acid, wet soils, but should not be applied to potatoes owing to the risk of scab disease with the increase in the content of lime. It should not be applied with sulphate of ammonia. Bonemeal is also slow acting and also contains some nitrogen. It is excellent for crops like tomatoes, and is also used extensively for ornamental and pot plants.

Potassium, the third major element, is essential for good flower colour and ripeness in fruits. Dessert apples, potatoes, cereals, and root crops all need potash in some quantity, and if excess nitrogen has been applied a dressing of potash may counterbalance the effect. Sulphate of potash is the main inorganic compound in use. Muriate of potash (potassium chloride), to which some crops are sensitive, is much less used; it should be applied as a winter dressing before the crop sown to lose the impurities by weathering. Su phate of potash is purer, and may be applie during the growing season at 1 oz. per sq. yd. o the vegetable plot, and is used in many proprietar fertiliser mixtures.

Wood ash contains variable quantities of pota sium, and provided that the ash has not bee washed by rain and the potassium leached out, is useful addition to the soil; bracken, cut durin June and July, when large amounts of potassiu are present in the foliage, can be composted whe green to provide a good supply of the element.

Elements Required in Lesser Quantity.—Ca cium, although required in small quantities in th plant, has profound effects on the soil. Its mai function in the plant is in the production of th cell walls, but in the soil it helps to bind ligh soils together and to make the structure of stick clay soils finer and more workable. Also soi without calcium are acid and tend to lock u some elements in an insoluble form. Addition calcium changes the acidity, making it slightl alkaline or neutral, and releases the locke elements.

Calcium is applied as some form or derivativ of calcium carbonate, commonly known as lim which can be obtained in various forms. Hy drated or slaked lime (calcium hydroxide) commonly used on clay soils, and chalk or groun limestone on lighter soils. Calcium is graduall leached from the soil, and it is necessary to repla it, or the soil becomes too acid and many cro will fail to grow. A normal dressing of lime for vegetable garden is about 4 oz. lime or ½ lb. cha per square yard every two or three years, and best applied in autumn as a surface dressing aft digging. It should not be applied together wit other fertilisers. The amount of lime will depen on the type of soil, but it must be remembere that most vegetables grow best on a slightly ac soil.

Gypsum, or calcium sulphate, is sometim recommended to supply calcium, but its solubilit is negligible, and it is preferable to chalk or lim stone only on soils containing salt due to s flooding. It has been used to help reclaim par of East Anglia flooded by sea-water during th storm surge of January 1953 by improving the so structure. Sulphur, as sulphates, and ma nesium, as an impurity in limestone, are usual present in sufficient quantities for the plant needs.

Trace Elements.—In the case of the tra elements most soils contain enough for th plant, but in certain circumstances deficienci occur. Iron on very alkaline soils is insoluble an as it is essential for the production of chlorophy deficiency results in the chlorosis of the leave It can be rectified by spraying the leaves wit "Sequestrene Plus," as can the lack of magnesiu and manganese, which may also be deficient acid soils.

Chlorosis in brassicas and marsh spot of pe are due to magnesium deficiency. Boron defic ency, often occurring on light, calcareous soi is responsible for brown heart of cauliflow and several other "diseases," mainly affecting t growing point. It can be rectified by applyi borax to the soil at about 1 oz. per 15 sq. y Zinc and copper deficiencies are unusual in En land, but lack of molybdenum has caused whipta disease of cauliflower. Only minute quantiti of the last three are required; more may poisonous to plants and animals.

Organic Manures.—It should be noted th most of the deficiencies will not concern t amateur, especially if he keeps the ground in go heart with ample organic manure, which contai all the plant foods necessary. Well-rotted far yard manure from cows and pigs is by far the be organic food, but is scarce now, good farme returning it to their own land, and generally t material offered is low in nutrients. Poult manure, which is rich in soluble nitrogen salts, excellent either applied direct to the soil (not the growing crop for fear of damage) or compost with straw.

Many substitutes have been devised to use in ace of manure, among them sewage sludge, best pplied some time before growing the crop, spent ops from breweries, dried seaweed, excellent for otatoes when supplemented by superphosphate, oot, rich in nitrogen, composted town refuse, and e waste organic animal products mentioned rlier. The organic matter in all these materials essential for maintaining the soil structure and nnot be replaced simply by artificial fertilisers.

Liquid manure, produced by suspending an old ck of animal manure or soot in water for a few ays, is useful for the amateur to apply to pot ants and to individual crops like sweet peas, matoes, and chrysanthemums. Leaf mould d peat can be used as a mulch and also to supply rganic matter to the soil. Sawdust in a well-otted condition is also useful for inclusion in mpost and as a mulch. It is emphasised that must be well-rotted, and it is advisable to apply nitrogen fertiliser, such as sulphate of ammonia, the same time.

Composting of organic refuse from house and rden is much practised by the amateur nowa-ys.

Compost-making.—The methods developed for aking compost heaps are many and various; ey depend on three basic principles, good aera-on, plenty of moisture, and a nitrogen supply for e decomposition bacteria. A fairly simple ethod by which much garden and house refuse n be utilised is as follows. An area about 9 ft. 4 ft. is marked out and all waste vegetable atter—weeds, lawn mowings, cabbage leaves, a haulm, straw, dead leaves, and hedge clippings -are put in this area and trodden down. Care ould be taken not to use diseased material but ass clippings and weeds which have been recently eated with hormone weed-killers may be applied. hen the heap is about 9 in. thick it is sprinkled ith sulphate of ammonia and superphosphate, at oz. of each per square yard (2 oz. of each for a 9-ft. 4-ft. plot) and any wood ash available, and en sprinkled with 4 gallons of water and covered ith an inch of soil. This process is repeated with in. layers of rubbish until the heap is about 4 ft. gh, when it is better to begin a second heap. A rinkling of ground lime may be given as each yer is added, but should not be applied until ter watering to avoid reaction with the sulphate ammonia.

The completed heap should be watered occas-nally, and after about a month or six weeks, if me permits, it can be turned completely over, atered again, and re-covered with soil. The ap may then be left until rotted, and the com-st can be dug in as required; any unrotted aterial can be used as a basis for a new heap. e time taken for rotting will vary with the me of year and material used, but generally a mpost heap made during the summer should available for autumn use, and one made during e autumn ready for spring use.

There are a number of compounds on the arket, known as compost makers, which are said accelerate the decomposition, but in general a ap made in the way described is eminently satis-ctory, and although requiring a certain amount labour, is the least expensive way of obtaining mus for the garden. This latter point is ex-emely important nowadays with the scarcity of imal manure and the high costs of both inorganic d organic fertilisers. Prices are, of course, not tic, but comparatively the organic manures, ch as dried blood, hoof and horn, and guano, are ore expensive than the inorganic salts, but these k humus, which is an essential of a well-cul-ated soil.

General Fertiliser.—Many firms supply com-und fertilisers containing given amounts of the in nutrients needed, in either liquid or powder m, and some are made up with quantities of rogen, potassium, and phosphorus suitable for ecific crops like roses, tomatoes, and chrysan-emums. A general fertiliser which can be made by the amateur is as follows:

7 parts by weight superphosphate.
5 parts by weight sulphate of ammonia.
2 parts by weight sulphate of potash.

All the ingredients are easily obtained from local sundriesmen, and a mixture of this sort will supply a good general feed.

Green Manuring.—Another method of enriching the soil with organic matter is green manuring, which has been practised for some time by farmers and can no doubt be adapted to the gardener's purpose. Green manuring consists of planting a fast-growing catch-crop and ploughing the mature crop back into the soil. Legumes are especially good for this, as certain bacteria in their roots can "fix" the nitrogen in the air. Field peas, sown at 4 oz. per sq. yd. and Italian rye grass at 2 oz. per sq. yd. are commonly used, and clover and annual lupins are also suitable.

If sown after an early crop on land needing organic matter the green manure may be dug in during late summer. Alternatively, if the land is not being cropped at all during the year two green-manure crops may be grown; an early sowing of field peas in April may be dug in during July, and a further sowing of field peas or Italian rye grass sown immediately after may be dug in following the first few frosts.

New chemicals often appear on the market at exorbitant prices and with fantastic claims as to their value as "soil conditioners" and the like. Contrary to this generalisation, in recent years a chemical known as "Gibberellin" has been used to increase the growth of certain plants. It is now available to the amateur, but should be used with care and mainly in a spirit of experimentation, as no conclusive proof of its efficacy has yet been put forward.

GARDEN PESTS.

Every garden abounds in insects and other small creatures, but comparatively few species are pests which feed on plants. The great majority are quite harmless, while many are positively beneficial and help to keep the number of pests under control by catching and eating them. Every good gardener should make it his business to be able to differentiate between friend and foe. This is not always easy, but the speed of a creature's movements may often provide a clue. Fast-running, active creatures, such as the black ground-beetle or the centipede, are usually beneficial, while the slow-moving and sluggish ones, *e.g.*, wireworms, aphids and caterpillars, are usually pests. This is by no means an infallible rule, but it is handy to remember when in doubt.

The good gardener should also get to know the pests which are most prevalent in his district and which can be expected to crop up year after year. The first principle of good control measures is to act while an infestation is still in its early stages and before a great deal of damage is done. When one knows what to expect, steps can be taken to prevent an attack or to stop it developing to serious proportions.

Also, from the experience of past years one can often forecast whether a pest is likely to become numerous enough to make chemical treatment worthwhile. Remember, insecticides can become an expensive item, and there is little point in using them if the damage is negligible. In these circumstances insecticides may eventually increase the numbers of pests, since the treatment will also have killed off many of their natural enemies which had hitherto kept the pests under adequate control. In addition, good cultivation and general garden hygiene helps to reduce the numbers of pests.

The common pests of garden plants can be roughly divided into four main groups.

I. Root Pests.—These destroy the feeding mechanism of plants or tunnel into fleshy tap roots, tubers, and bulbs. Attacked plants make poor growth, and may eventually wilt and die.

Some insects are general root-feeders. These include (*a*) **Swift Moth Caterpillars**, soft, white caterpillars with reddish-brown heads; (*b*) **Chafer Grubs**, large, C-shaped, whitish grubs with chestnut-brown heads; (*c*) **Wireworms**, long, cylindrical, yellowish-brown grubs with a hard shiny skin; and (*d*) **Leatherjackets**, greyish-black grubs with a wrinkled, leathery skin. These are particularly prevalent in recently cultivated grassland or in gardens surrounded by fields, and will attack the roots of a wide range of plants. Chafer grubs, however, are particularly fond of the roots of shrubs, and wireworms will often tunnel in potato tubers and other fleshy roots, whereas leatherjackets prefer the roots of grasses, and may cause browning on large patches of lawn.

Badly infested ground should be dressed with lindane dust when cultivating, working the dust into the top 4 in. of soil. Where this is not possible, *i.e.*, on lawns or around established shrubs, the liquid form of the insecticide should be watered into the soil.

Cutworms are stout, fleshy caterpillars, varying in colour from greyish-brown to dingy green. They feed on roots during the day, but at night come to the surface and feed at the base of the stems of plants, causing them suddenly to collapse and wither. Brassicas and lettuce are commonly damaged in this way. Infested ground should be dusted with D.D.T.

Millepedes are hard-skinned, cylindrical creatures, brown or black, with numerous short, hair-like legs. They are slow-moving and curl up when disturbed. They should not be confused with the active, long-legged centipedes, which are beneficial. Millepedes commonly extend the damage made by other pests, such as slugs and wireworms. They also bore into the sown seeds of peas and beans. During the day they hide in dark, damp places, such as long vegetation or under stones and pieces of wood. Such hiding-places should be removed or dusted with lindane. Drills for pea and bean seed should also be dusted before covering.

Weevil Grubs, small, curved, white grubs, may infest the roots of pot plants and plants in rockeries. Such plants should be removed, the roots cleaned, and replanted in soil which has been dressed or mixed with lindane dust. Where it is not practicable to remove the plants they should be watered copiously with a liquid form of these insecticides and soil dressed properly at the earliest opportunity.

Slugs need no description. They vary greatly in colour. The most destructive are the underground keeled slugs, small, grey-black in colour, which tunnel in roots, tubers, and bulbs. There are also several foliage-feeding species which rasp holes in the top parts of plants. Slugs like wet conditions, and much can be done to control them by ensuring that the soil is well-drained and that long, tangled vegetation is removed.

Poison baits can be bought or made by mixing 1 oz. metaldehyde with 3 lb. bran (or bonemeal for keeled slugs). The bait is sprinkled over the infested ground or distributed in small heaps and protected from the rain. There is also available on the market a metaldehyde spray for dealing with the foliage-feeding types.

Cabbage Root Fly attacks brassicas and wallflowers. The small white maggot eats away the side roots and tunnels in the main root, causing the plant to wilt and collapse. The roots of young seedlings should be dipped in lindane before planting out. Alternatively, the plants can be given a drench of lindane within four days of planting out.

The maggots also tunnel in radishes and turnips, and this can be avoided by dusting the seed drills with lindane.

Carrot Fly.—The maggot of this fly tunnels in carrots and parsnips. Where the pest is serious it is best to delay sowing until the end of May. If possible, seeds should be sown in exposed, windy places, which are avoided by the egg-laying flies. Seedlings should be dusted or sprayed with lindane when 2–4 in. high, particularly in late May or early August, the peak periods for egg-laying.

Onion Fly maggots tunnel into the bulbs of onions, leeks, and shallots, causing the foliage to collapse. Dig out attacked plants carefully, ensuring that parts of them are not left in the soil, and burn them. To prevent attacks dust around the seedlings with lindane when they are at the "loop" stage, *i.e.*, about 1 in. high, and again ten days later.

Narcissus Bulb Flies are serious pests of narcissi and also snowdrops and other bulbous plants. The maggots burrow in the centre of the bulbs, causing them to rot. All soft bulbs should be burned and the remainder immersed for three hours in a solution of lindane containing a wetter. To prevent future attacks and a reinfestation, dust around the necks of growing bulbs with lindane at fortnightly intervals from the end of April until the end of June.

Insects which feed above ground include:

II. Sucking Pests pierce the tissues of plants with needle-like mouth parts and suck the sap. This devitalises the plant, checks growth, and causes wilting. Some species cause distortion of leaves and young shoots, and aphids, suckers, scale insects, and mealy bugs excrete a sugary fluid which disfigures the foliage, attracts ants, and allows the growth of sooty moulds.

Aphids, *i.e.*, blackfly, greenfly, etc., are serious pests which attack almost all plants and multiply rapidly in warm weather. They feed on the shoots and undersides of the leaves, and many species are responsible for the transmission of virus diseases. Infestations should be treated as early as possible. Malathion, lindane, D.D.T. emulsion, and nicotine are all good sprays to use, and should be applied to the undersides of the leaves. With the advent of these sprays the control of aphids on roses and broad beans, for example, is no longer a serious problem.

Tree fruits should be sprayed when the buds are bursting and again when the flower buds are still green. Currants should be treated at the "grape" stage, but lindane should not be used on this fruit. Tar oil, applied to deciduous woody plants while they are completely dormant, will kill the overwintering stages of these and many other pests. It does not, however, give a good winter control for **Woolly Aphid** on apples. This pest is best controlled by spraying at the pink-bud stage with B.H.C. with a succinate spreader added. Small colonies on the bark can be eradicated by painting with 10% tar oil.

Some aphids feed underground on roots, particularly of lettuces, currants, and cacti. Where practicable, infested plants should be lifted and the roots cleaned and sprayed before replanting in clean soil. Otherwise water them copiously with malathion or lindane.

Scale Insects are often found in greenhouses but also occur out-of-doors on trees and shrubs. Flat or dome-shaped, these creatures spend most of their lives immobile, and they do not at al resemble insects, or even appear to be alive. Again tar oil is useful for killing the overwintering stages on deciduous woody shrubs which are dormant. Plants which are in leaf should be sprayed with malathion or nicotine/white oil emulsion two or three times at fortnightly intervals. These substances are more effective if as much as possible of the scale is first removed by means of a sponge, brush, or scraper with water in which soft soap has been dissolved. **Mealy Bugs** are common pests of greenhouse plants, and should be given the same treatment as scale insects.

Capsid Bugs are very active insects which cause considerable damage to fruit trees and bushes and also to various ornamental plants, principally ysanthemums and dahlias. They feed on the ing leaves, causing distortion and raggedness, l on the buds, which later produce misshapen oms. These insects, green or reddish in colour, be controlled by spraying with lindane or D.T. when the flower buds are still green (tree it) or with D.D.T. at the "grape" stage (curts). Herbaceous plants should be sprayed two three times at three-weekly intervals, starting en the plants are young and before the damage een. The ground under the plants should also sprayed to kill those insects which fall off during atment.

eafhoppers are small, yellowish-green insects aphids but much more active. They feed the undersides of the leaves of a variety of nts, causing them to become speckled with low. Roses are commonly attacked. The atment given to capsids on herbaceous plants l control these also, the sprays being directed the undersides of the leaves.

Whiteflies are serious pests in greenhouses, and o occur out-of-doors on rhododendrons and er evergreen shrubs. The adults are like niature moths with white wings, and the young small, scale-like creatures, generally greenish colour, which feed without movement on the dersides of the leaves. To control this pest D.T., lindane, or malathion should be used as pray or smoke, two to three applications being en at fortnightly intervals.

ed Spider Mites are extremely small creatures, or greenish in colour and just visible with the ked eye. They feed on the undersides of the ves of many greenhouse and outdoor plants, luding fruit, causing the leaves to turn sickly low. Control is difficult, the most effective terials being malathion, derris, summer ovies, or azobenzene smoke. The directions on labels of these products should be followed efully.

I. Biting Insects have chewing and biting uth parts which are used to cut away pieces of nts.

aterpillars (the young stages of moths and terflies) are the best-known pests in this group. ey vary in size and colour according to the cies, and most plants are liable to be attacked. ese should be sprayed or dusted with D.D.T. derris as soon as damage is seen. On fruit es D.D.T. should be used when the fruit buds still green, and again at the pink-bud stage if infestation is serious.

he **Codling Caterpillar**, which tunnels in apples, ontrolled by spraying with D.D.T. at the end of e and again three weeks later. Since this latter atment tends to encourage red spider mites, it is isable to add to the D.D.T. one of the materials ommended for these pests.

awfly Caterpillars are very similar to those ve, and commonly attack gooseberry and rose age. They can be controlled by spraying with D.T., derris, or lindane. Attacks by the **Apple fly**, which burrows in young apples and forms oon-like scars on the skin, can be prevented by aying with lindane seven days after 80% of the ssom has fallen.

eetles and Weevils which feed on foliage are ally best controlled by spraying or dusting h D.D.T. To kill the tiny **Flea-beetles** which small holes in the seedlings of brassicas and nips, treat the plants at fourteen-day intervals il they reach the "rough-leaf" stage.
he golden-brown **Raspberry Beetle**, which feeds he flowers and whose grub tunnels in the fruit, radicated by D.D.T. or derris applied ten days r full bloom and again ten days later. For er common pests in this group, *e.g.*, **Vine evil, Clay-coloured Weevil, Pea and Bean evil**, etc., apply the D.D.T. as soon as the nage is first seen.

Earwigs feed at night on the foliage and flower petals of many plants. They hide by day inside flowers, in the folds of leaves, and in nooks and crannies on the ground, under flat stones, etc. These pests are killed by D.D.T., applied to the plants (but not to open flowers) and to their hiding-places.

Leaf Miners are very small grubs which tunnel between the upper and lower surfaces of leaves, forming pale blisters, as on lilac, holly, celery, etc., or long, twisting galleries, as on chrysanthemum, pea, and tomato. In small infestations the affected leaves should be picked off and burned. Otherwise spray with lindane as soon as the damage starts, giving three applications at fourteen-day intervals.

IV. Eelworms are microscopic pests which are invisible to the naked eye. They are able to live for very long periods without food and are extremely difficult to eradicate. The most common species are:

Stem and Bulb Eelworm, which infests narcissus, phlox, strawberry, hyacinth, onion, and other plants. Infested plants show distorted foliage and dwarfing and gradually deteriorate. They can only be sterilised by immersion in hot water kept at well-defined temperatures for one to three hours, but expert diagnosis and advice should be obtained before this or any other control is attempted. Infested ground must be kept clear of any host plants for at least three years to starve out the eelworms.

Chrysanthemum Eelworm causes the formation of yellowish blotches between the veins of chrysanthemum leaves, which later turn black and drop off. In severe infestations the blooms are undersized and malformed. Expert advice should be obtained before control measures are attempted.

Potato Root Eelworm is a serious and widespread pest of potatoes, causing the plants to become stunted and sickly, giving very poor yields. The pest can only be kept in check by crop rotation, potatoes being grown on the same ground only once in four years. This is difficult in small gardens, and where land becomes heavily infested the only remedy is to rest it from potatoes for at least five years.

The Purchase and Use of Insecticides.—To ensure that an insecticide will do what the maker claims, it is advisable only to buy brands which have been tested and approved by the Ministry of Agriculture. This can be ascertained by the presence of an Approval Mark (**T30**) on the label. Read the directions and follow them carefully. Over-strength insecticides can cause damage to plants, and certain plants (usually listed) can be injured by some insecticides at any concentration, *e.g.*, cucumbers, marrows, etc., by D.D.T. and lindane. Never apply insecticides to flowers in full bloom, otherwise many valuable pollinating insects will be killed.

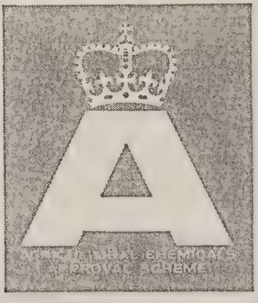
DISEASES OF PLANTS.

Plant diseases are important because they can cause great loss not only in growing crops but also in the produce after it has been harvested and stored. The skill in growing crops is wasted if they are destroyed by disease, and many people know the wastage of potatoes through blight disease in winter stores and rotting of onions when they decay through neck rot disease. For these reasons the keen gardener must take notice of diseases and use the knowledge available to him in checking them wherever possible.

The most important point to remember about plant diseases is to recognise the first signs so that the remedy can be applied at once. In greenhouses this is of great importance because the atmosphere is warm and moist, and in such conditions diseases flourish. It must also be remembered that the same crop is often grown in the same soil in a greenhouse so that we get a build-up of disease, and this causes the well-known "soil sickness." This means that new soil must be brought in or the old soil enriched and also sterilised by steam or by chemicals. Even frames and propagating pits require periodic cleaning up by a disinfection treatment.

Unlike insect pests, the actual cause of a plant disease cannot be seen with the naked eye, and microscopic examination is required for its detection. The scientists who study diseases are called plant pathologists, and these are stationed at universities and other institutes throughout the country, where they carry out research on various plant troubles and advise on suitable remedies for checking them. It is obviously necessary to understand the exact cause of a disease and how that cause operates before a means of checking the trouble can be devised. The advice can then be passed on to growers, farmers, and the gardening public.



The Approval Mark—An officially approved crop-protection product shows on its label this design.

The presence of disease in most cases can only be detected by the symptoms shown by the affected plant, which is called the "host" plant. The actual cause must then be determined by careful examination in the laboratory, which is done by the pathologist.

Plant diseases in general are divided into three classes as follows: 1. Fungus and Bacterial. 2. Virus. 3. Functional Disorders.

1. Fungus and Bacterial Diseases.—The first kind called fungus diseases are caused by the attack of fungus parasites; examples being the well-known club root of cabbages, potato scab, apple scab, and plum brown rot. These parasitic fungi are microscopic and composed of fine threads, but they attack plants and penetrate them either through wounds (insect bites, hail damage, pruning cuts) or directly through the surface cells (epidermis). The threads grow into the plant, killing the cells and absorbing their contents. There is usually some discoloration or even decay of the tissues around the point of infection, but it is possible for the plant to show distress in one part although the parasite is at work some distance away. Examples are silver leaf in plums and the honey fungus, which kills trees by attacking the roots.

The fungus spreads by means of spores which are equivalent to seeds in flowering plants but which are microscopic in size. These spores are produced on the surface of the plant in enormous numbers and are blown (wind), splashed (rain), or carried (insects, etc.) in all directions to alight on other healthy plants, where they germina
and spread the disease. This occurs in the grov
ing season, but when winter approaches, tl
parasite forms tough, resting bodies of one ki
or another, and these are resistant to extreme col

They overwinter in the soil or in the surface
tree bark, etc., so that in the following spri
they can germinate and cause disease agai
So we get the reappearance of such troubles
damping off in seedlings, scab in apples, brown r
in apples and plums, foot rot in peas, wart disea
in potatoes, mildews on all kinds of plants, ar
so on. This question of soil contamination l
overwintering spores is one of the most serious
the fight against plant disease.

The signs of fungus and bacterial diseases a
varied, and may show as yellowing, silverin
brown spotting, or blackening of leaves (pota
blight, rose black spot, celery leaf spot, anti
rhinum rust), as stunting (cabbage wire stem),
pustules and cankers in stems (coral spot, app
canker), as gumming or dieback in branches (ro
canker, plum dieback), as galls, warts, witch
brooms, or other malformation (club root in ca
bages, crown gall, leafy gall, peach leaf curl),
dry or soft rots of fruits, tubers, vegetable bulb
and corms (gladiolus dry rot, potato dry rot, i
rhizome rot, celery heart rot), and many oth
abnormal conditions. Sometimes only a part
the plant is affected and can be removed, *e.*
branches showing attack by coral spot or one of t
large bracket fungi seen on trees, these havi
gained entrance through a wound.

2. Virus Diseases.—This class of disease
becoming increasingly important as more is di
covered about them, although research on the
is a comparatively recent development. A vir
disease is caused by infection with a virus, a
the exact nature of this is not yet clearly unde
stood, but it is so small that it cannot be seen wi
ordinary microscopes. Its detection is therefo
not easy, but when the sap of a virus-diseas
plant is injected into a healthy one it causes t
disease.

In nature this spread is brought about
biting and sucking insects, which are referr
to as Vectors. They transmit the virus by feedi
on infected plants and then travelling to healt
ones, on which they feed and so spread t
disease. Most viruses are transmitted by aphi
(greenflies).

In the garden and nursery they can be carri
from plant to plant by pruning knives or by t
fingers in the process of trimming plants such
tomatoes, melons, and cucumbers or by the u
of the knife in taking cuttings. In general, t
virus does not kill a plant quickly but tends
cripple it and cause a slow deterioration. Infect
plants cannot recover but remain, sometimes f
years, as sources of infection on which inse
feed and carry on the disease. So viruses m
increase in lily stocks, strawberry beds, and ras
berry plantations unless virus-infected plants a
removed and aphids strictly suppressed.

The signs of virus disease are of different kin
but the commonest are those of the type call
mosaic, in which the leaves show a mottling wi
light-green or yellow patches scattered in irregul
fashion on the darker green of the leaf. The
may be also some reduction in the leaf blad
These symptoms can be seen in the mosaic
cucumber, vegetable marrow, lettuce, cabba
turnip, tomato, delphinium, primula, dahl
apple, raspberry, and many other common plan
In some, such as lilies, daffodils, and onions, t
mosaic is more in the form of stripes down t
leaf blades.

Another virus symptom is flower "breakin
where the normal colour of the petals is brok
by streaks and spots of white, and this can be se
in tulip, wallflower, pansy, stocks, or carnatic
affected by the mosaic virus. Other viruses ca
bronzing of the top leaves (as in tomato spott
wilt) or small light-coloured rings arranged
concentric circles (as in dahlia ring spot) or ev
reduction of leaves until they are tendril like
in tomato fern leaf). Sometimes there is m
formation or even proliferation, producing
numerable stunted shoots, as in blackberry dw
disease.

The important point to note about these vi
diseases is that every part of the plant is quic

fected, so that the sap is infectious to other ants of the same kind. The virus is present in parts, and for this reason it is useless to propa- te from a virus-infected plant. This means that the scales and offsets from bulbs such as lilies d tulips, all the tubers from potatoes, and all ttings from herbaceous plants which are taken om a virus-infected plant are useless, because ey will carry the virus. They should be stroyed, and the only exception is where the ant is greatly valued, in which case seed can be ken from it before it is destroyed. In general, ruses do not travel in the seed, and only in one two cases is seed infected, and this only in gligible quantity.

3. **Functional Disorders.**—This third class of sease is often called non-parasitic, because un- e the previous two kinds there is no parasite volved, and these troubles are therefore not fectious. They are due to faulty cultivation or suitable environment, in which soil conditions climate affect the plants adversely. In this oup we include cases of unsatisfactory growth e to waterlogging, drought, frost, high tem- rature, damage by fumes or atmospheric pollu- n, or even excess lime.

Perhaps the most important kinds of trouble in s class are the so called **Deficiency Diseases,** ere the plants suffer from shortage of some im- rtant food. This may be one of the common od substances, such as nitrogen, potash, or osphate, and details will be found under the tion on manures and fertilisers (T25).

CONTROL OF DISEASES.

1. **Garden Hygiene.**—The control of plant eases can be dealt with only briefly, but to gin with we must emphasise the value of good ltivation as an insurance against losses from sease. Robust plants are better able to nd up to disease than sickly ones, and every- ng in the way of proper drainage, soil aeration, oper spacing, sensible feeding, and so on, l help to keep the plants vigorous, and this the first line of defence against diseases. rden hygiene is important, weeds need to be pt down, wounds in trees and shrubs covered th a good paint against infection, new stocks amined carefully, seed bought only from reliable rces, diseased plants burnt, and dead material gularly removed from plants, especially in eenhouses.

2. **Soil Sterilisation.**—There are other pre- tions, among which the sterilisation of the soil greenhouses by means of steam or chemicals of some importance. Outdoors this is not ssible, but rotation of crops is a most useful tem in helping to avoid disease. Disinfection frames, propagating pits, and seed boxes by malin or cresylic acid are other useful measures. All these operations aim at destroying the ting spores of fungus parasites responsible such diseases as tomato leaf mould, gladiolus rot, damping off in seedlings, root rots, and wny mildews of many kinds in young plants ch as stocks, cheiranthus, cineraria, tomato, er, and calceolaria when grown in boxes or ts.

3. **Disease Resistant Plants.**—The use of disease- istant varieties of plants is very desirable, but re are not many kinds available, and often the istant kind does not possess flowers or fruit of h fine quality or flavour as the more susceptible d. The outstanding success of this kind is that potatoes immune to the dreaded wart disease, l these can be grown safely in the most heavily ected land. There are antirrhinums resistant rust disease, and there is resistance in some ree in the case of delphinium mildew, potato ght, tomato leaf mould, and some others. search goes on to discover still more, because such plants are always worth a trial.

4. **Treatment of Seeds and Bulbs.**—For seed- ne diseases seed treatments may be done with an organo-mercurial seed dressing, or even by immersion of the infected seed in warm water.

In some diseases, for example, tulip fire, we can protect the bulbs from the danger of infected soil by raking in a powder such as "Botrolex" when planting the bulbs, and a similar treatment is done with calomel dust against club root in beds intended for sowing brassica seeds.

5. **Fungicides.**—Even after all this, a disease may still appear in the crop, and more direct action must be taken. It is then necessary to protect the plants by means of a **Fungicide.** This is a chemical which is poisonous to fungus parasites but which will not harm the crop plant (host). Fungicides are used as wet sprays or in powder form as dusts, and they are sprayed or dusted all over the plants to protect them from infection by diseases.

The object of the treatment is to cover the plants with a film of the fungicide so as to protect the still healthy ones. To help the spray fluid to spread over and adhere to the foliage another substance, called a wetter, spreader, or sticker, is added to the spray, but sometimes this is already included by the manufacturer.

5. (*a*) **Sprays.**—Sprays are applied by means of machines called sprayers which vary from small, hand-syringe types giving a continuous jet of spray to those pumped up to a pressure and carried on the back (knapsack machines), and so on to the large machines driven by a petrol engine, which deliver the spray at a high pressure. It is necessary to have a suitable nozzle giving a fine mist-like cone of spray which settles on the foliage and is not wasted.

5. (*b*) **Dusts.**—Dusts are similar chemicals produced in such finely divided form that the powder can be blown over and on the foliage almost like a fog. This is best done after a shower of rain or after a heavy dew. The machines used are far more varied in design than spraying machines. There are small hand dusters worked either like a small pump or like a bellows, of which the "Acme" is a good example, and there are those which are carried on the back and worked as a double-bellows action or on the front of the body with a rotary-fan action. It is important in gardens to clean and dry the machines after use, and small sprayers may be best put upside down to drain for a time after use.

The substances used as sprays and dusts against plant diseases for many years have been copper and sulphur and their compounds. Perhaps the best known copper-containing spray is "Bordeaux Mixture," which is still a good spray, but which has been largely replaced by colloidal copper available under trade names like "Coppicide" for such diseases as tomato blight, etc. Sulphur is used extensively as lime-sulphur against apple scab and as colloidal sulphur against the powdery mildew diseases. As dusts, copper is mixed with lime to give copper–lime dust and sulphur is used alone either as flowers of sulphur or green sulphur.

5. (*c*) **The Newer Fungicides.**—In recent years much research has been carried out in tests to see whether other chemicals have value as fungicides, and the search has been in the field of organic chemistry and among all kinds of these chemicals. Tests of this kind take a long time, but a few substances have already been picked out as showing great promise, and we can mention "Captan," which is so good against apple and pear scab, "Zineb" aginst tomato leaf mould, onion mildew, and tulip fire, "Karathane" against any of the powdery mildews, such as american gooseberry mildew, strawberry mildew, vine and peach mildews, as well as the same diseases on ornamental roses, delphiniums, michaelmas daisies, and the like.

6. **Control of Viruses.**—The control of virus diseases is very different, because in this case the only spray treatments likely to be of use are those designed to keep down insects. The other necessary control measure is to remove and destroy the virus-infected plants, which are a danger as sources of infection.

This is best done when the plants are young, so that any young marrows, cucumbers, dahlias, delphiniums, sweet peas, lupins, lilies, etc., which show virus symptoms as commonly revealed in leaf mottling and poor growth should be removed as soon as detected. Propagation should be done carefully, so that young stock is not propagated from stocks of strawberries, raspberries, and all kinds of herbaceous perennials which show signs of virus infection. Even the knife used for taking cuttings should be wiped occasionally on a rag dipped in a good disinfectant.

7. Prevention of Functional Disorders.—In the case of Functional Disorders (non-parasitic diseases) it is not always easy to advise remedies. Where the soil conditions are faulty attention can be directed to improving drainage if necessary or counteracting dryness by digging in humus, irrigating, and general mulching. Dryness at the roots of tomatoes causes loss of fruit, and so does extreme dryness in the air of the greenhouse, but these should be adjusted fairly easily.

Hail damage can spoil many crops, but robust foliage may help a little to lessen the damage. Late frost damage to fruit in some areas can be lessened by various methods of cultivation and planting. The effects of drought can be aggravated by shortage of certain foods, especially potash, so that even here some attempt can be made to avoid loss. Excess liming may cause food shortages by causing the appearance, in the leaves, of a yellowish or even whitish colour, which is known as lime-induced chlorosis. The real reason may be lack of iron or manganese due to the excess lime in the soil, but recently very good results at counteracting this condition have been obtained by using the substance known as "Sequestrene Plus."

Another method of treating these food shortages is to spray the young foliage in early summer with the required element in a very weak solution. They can even be included in sprays used for keeping down diseases or pests. It must not be forgotten that even the ordinary foods, such as nitrogen, potash, and phosphate, may sometimes be in short supply, and the effect can be seen by the trained plant pathologist. In these cases the effect may not always show clearly in the growing crop, but may appear long afterwards in the stored fruits and vegetables, which as a result deteriorate and break down long before they are required for use.

The present-day methods of cultivating large numbers of the same plant in one spot tend to increase the risk of large-scale disease attacks. Modern plants may be highly bred and selected for great purity of strain. Indeed, they have often been chosen for fine quality and flavour, with little regard to their ability to resist disease, so that the gardener must always be ready to give them the protection they may need.

USES OF MODERN WEEDKILLERS

The eradication of weeds by chemical means is one of the greatest advances of recent years albeit the value of herbicides is still unappreciated by most gardeners. With a planned programme, all cultivated ground and lawns can be kept free of weeds without hoeing or any other sort of manual cultivation.

Occasionally troubles have arisen in not following makers' instructions. Sometimes the damage has been most unfortunate, as the majority of herbicides are toxic, in varying degrees, to a wide range of plant life. In the main, controls are determined by circumstance, as typified in the following cases:

Asparagus Beds.—Annuals and top growth of perennial weeds can be controlled with cresylic acid in the autumn and before the asparagus appears in the spring. In beds free of perennials, a first-class control of weeds can be maintained wit
Simazine applied in the early spring.

Where annual and perennial grasses predomin
ate, Dalapon or Diquat will give good contro
As for bindweed, this may be eradicated by water
ing the foliage with 2,4-D in late July or Augus
taking care to avoid contact with the asparagu
stems and particularly the fern.

Fruit Garden.—Around blackcurrants, goose
berries, raspberries, apples, and pears, grasses ca
be killed with Dalapon. Once clear of perennia
weeds, annuals may be controlled effectively wit
Simazine. Alternatively, weeds may be kille
with Diquat, making applications as necessar
throughout the season.

Garden Paths.—On any surfaced path or driv
a first-rate control of weeds can be maintaine
by watering with a residual herbicide such a
Simazine. As this preparation is virtually in
soluble in water, it does not seep through the so
as sodium chlorate would, and therefore it can b
used near garden crops and grass edgings. Fu
ther to this, it is not easily washed from the so
and remains active near the surface for up t
twelve months. Notwithstanding, the herbicid
must be used with proper care.

A dilute solution of sodium chlorate with 4–
ozs. to a gallon of water may be applied, but it
liable to affect plants near by and, for this reaso
application should be confined to the centre of th
path, thereby leaving room for the chlorate t
seep through the soil.

Lawns.—The majority of weeds in turf can b
eradicated easily with formulations of 2,4-D o
M.C.P.A. (*see* **Finding List**). In particular, daisie
dandelions, plantains, and most broad-leave
weeds are susceptible although it may be neces
sary to repeat the dose after 10 days. The bes
time to do the work is on a warm, fine day in th
spring when the plants are growing actively an
there is the prospect of fine weather to follow fo
twenty-four hours. The action of the herbicide
is rapid, and grass may be cut after a couple o
days, composting with mowings in the norma
way. It appears that the hormones are no
injurious to bacterial life in the soil and in a fe
weeks break down into harmless substances.

Where bulbs are naturalised in grass, steps t
control weeds should not be taken until the folia
of the bulbs has died down and the bulbs a
dormant. Thus, as a general rule, control mea
sures are best applied throughout July.

To deal with weeds in turf where there arise
the danger of the spray—or even a drift from it–
touching cultivated plants near by, as, for in
stance, on grass paths in a rose garden, then
wax bar impregnated with a hormone can b
lightly drawn over the turf. Such bars are avai
able at a reasonable price under trade names lik
"Supplex Touchweeder."

Some weeds are resistant to normal doses o
hormones and need special treatment. These a
mostly mat-forming plants of low-growing hab
which are not cut off by mowing. Typical ex
amples include mosses of all sorts, pearlwor
speedwell or veronica, yarrow, and yellow
flowered clover. Here, the main control must b
in the use of lawn sand, a good mixture of whic
can be made up with:

2 parts by weight sulphate of ammonia.
1 part by weight sulphate of iron.
13 parts by weight LIME-FREE sand.

Where moss is the most prevalent weed, to th
mixture should be added sufficient superphospha
to give 1 oz. of it per sq. yd. for the area to b
treated. A hundredweight of the lawn sand pl
superphosphate can be made up for about 17*s*. an
is sufficient to treat about 450 sq. yds. at 4 o
per sq. yd.

Applications to patches of the weeds should b
made when the turf is damp and there is th
prospect of fine weather; if a period of droug
follows an application, then water should b
applied to avoid serious scorching. Repeat th
treatment as necessary throughout the growi
season. Linked with this "spot" treatment, th
growth of grass must be encouraged, as this w
tend to smother low-growing weeds. Thus, in th
early spring when the turf is wet, feed with

ture of equal parts of superphosphate, sul-
te of ammonia and dry soil at 2 oz. per sq. yd.
r the whole area and repeat after a month, if
rable. In addition, do *not* shave off the grass
close cutting; instead, the blades of the mower
ıld be set reasonably high for a whole season.
/here fertility is low, clovers often predominate
ırf. The Dutch clovers with white—or pink—
ers and a white-angled band towards the base
ach leaflet, can be eradicated with Mecoprop.
erwards the turf should be fed with nitrogenous
ilisers like soot and sulphate of ammonia, to
ourage reinfestation. Other types of clover
ıd in turf are species of *Trifolium*. Compared
he Dutch clover, these have a tight, bunched
it of growth and yellow flowers. All of them
resistant to hormones and, in addition to
ıurial treatment, should be treated with lawn
l.

akes.—It sometimes happens that aquatic
ıts with large floating leaves, such as water
s, get out of hand. Here, control can be
blished by cutting off the foliage with a long-
dled appliance like the "Corypu Water
he." The work should be done early in June
repeated as often as any fresh growth is seen.
ulrushes are difficult to eliminate, but can be
royed by digging out the roots when the level
ne water permits. Dalapon has been found to
a control; applications should be made, with
etting agent added, when the rushes reach
ırity.

onds.—Problems of weed control in ornamen-
ponds are often not easy to solve. Where
kweed is prevalent this small floating plant
be eliminated by sweeping the surface of the
er at regular intervals. If this practice is
ied out thoroughly much of the vegetative
rth will be eliminated, and the plant will not
ble to form resting bodies whereby it over-
ers. Once a control has been established,
ner spread of the plant can be prevented by
oducing a few moorhens or ornamental ducks.
ne most common of unwanted plants in pools
lanket weed. There is no single means of
ng with this plant, for its spread is governed,
certain extent, by unbalanced plant and
a life in the water. With this fact in mind,
r lilies should be established so that their
ge shades about 25 per cent of the water.
ddition, a few oxygenating plants should be
duced from local ponds or streams and a
ly of goldfish added. Blanket weed is
lly found in pools where the water gets over-
ed in summer; for this reason, the average
h of garden ponds should be a minimum of
and preferably a minimum of 3 ft.

ose Beds.—A complete control of annual weeds
ng roses can be obtained with Simazine.
, the salient point is to apply the herbicide
ediately after pruning in March *before* any
growth starts. Alternatively, Diquat can
ed in April or early May and the application
ted as necessary.

rubberies.—With a shortage of labour, beds
rubs are often weed infested. Perennials can
adicated with Diquat and annuals controlled
ıis treatment as they appear. Alternatively,
the perennials are removed, the ground can be
clear with Simazine used in the early spring.
ıch to check weeds in shrubberies can be
by mulching the surface of the soil with
y dressings of peat, fallen leaves, or sawdust;
e weeds push through the mulch, a second
cation should be made at once.

cant Ground.—On land free of crops all plants
e killed by watering the herbage with sodium
ate at 1 lb. to a gallon of water. In some
repetition may be necessary. When using
nethod it should be remembered that treated
d will remain toxic to plant life for a period
to six months; if doubt exists about the
tence of the chlorate in the soil, then it is
able to wait for the appearance of annual
s before planting.
art from its persistence, sodium chlorate is
to seep through soil and affect plants for
distance away. To avoid danger of fire from clothes being soaked in a solution of the chlorate and then dried, it is prudent to use a formulation with an additive to reduce the risk of fire. (*See* **Finding List.**) Where couch grass is predominant then the best control is to be obtained with Dalapon.

SPECIAL PROBLEMS OF WEED CONTROL

Bindweed.—Probably the most ubiquitous of all garden weeds. Up to the present time the main control has been to carefully fork out the roots as new growth is seen; if this is done methodically the plant can be eliminated within a reasonable time.

Lately, chemicals have come to the fore, and bindweed may now be eliminated by watering or painting the foliage with a formulation of 2,4-D when the annual growth has nearly reached maturity. Thus, first applications can be applied in July and the treatment repeated, if necessary, to good effect. Where the weed is among cultivated plants, the herbicides must be applied with a paint brush or the foliage rubbed with a cloth damped in a solution. When doing this rubber gloves should be worn.

Blanket Weed.—*See* **Ponds.**

Bracken.—Horticulturally, control is not a big problem, and in limited areas it is easily dealt with by repeatedly cutting the aerial stems with a grass hook as the first fronds open. This practice will exhaust the underground food supply of the plant, and gradually it will die out. The young fronds are rich in plant food and, while still green and fresh, they should be composted. No chemicals will offer a reasonable control of this plant and, indeed, it is best dealt with by cutting and final digging out of the roots.

Couch Grass.—Where the soil is light and tends to be low in fertility, it is often found that this is a difficult plant to eradicate by cultural means. If the long, underground stems are forked out in the conventional manner and left on the surface to dry, the roots may be composted to advantage and a good control established. To prevent reinfestation, manures and fertilisers should be applied generously and the ground kept hoed regularly.

Chemically, couch grass can be killed easily by watering the foliage with Dalapon.

Ground Elder.—Without question this is one of the worst garden weeds and, whether or not the fact is pleasant or acceptable, it is indubitably a weed of neglected ground. In varying degrees it is resistant to hormone weed-killers of all sorts. On ground free of crops it may be reduced by an application of sodium chlorate, as explained in the paragraph **Vacant Ground.** The first treatment should be made as soon as growth starts in the spring and repeated if the desired effect is not abundantly clear. When ground elder is to be found among herbaceous plants the cultivated plants must be lifted out and the weed removed by repeated hand-forking.

In shrubberies reasonable control can be had by smothering the young growth in the spring with a thick dressing of peat, leaf mould, baled straw, or sawdust. If growth penetrates the surface dressing it will be found that the etiolated shoots are not difficult to remove by hand, or a second layer can be applied to complete the treatment.

Alternatively, the foliage of ground elder can be watered with Diquat and the treatment repeated once or twice during the growing season.

Horsetail.—This is sometimes erroneously called marestail and on poor, sandy soils it is often a common weed. Fortunately, recent experiments have proved that it can be easily controlled by spraying or painting the *mature* growths with a formulation of 2,4-D, taking care, of course, to keep the spray off cultivated plants near by. As the appearance of horsetail is symptomatic of low fertility, manurial treatment should be carried out on a generous scale. Where the weed is growing among cultivated crops, individual stems must be treated separately as recommended for bindweed.

Marestail.—*See* **Horsetail.**

Moss.—*See* Lawns (T32).

Nettles.—It is difficult to understand why the perennial nettle is so abundant as it is immediately responsive to applications of 2,4-D and 2,4,5-T made any time during the growing season. The annual nettle is usually proved a denizen of rich, light soils and may be eradicated with cresylic acid, Diquat or 2,4-D.

Oxalis.—Of all weeds this is probably the most difficult to destroy. It is easily identified by its large, trifoliolate leaves like that of clover. Unlike other weeds, oxalis cannot be efficiently removed by hand, as this disturbs the bulbils clustered around the base of the stem of mature plants. On ground free of crops, sodium chlorate can be applied in March (*see* Vacant Ground). Perhaps a second application may be necessary, but, even so, control may not be complete. Among shrubby plants, it may be possible to eradicate the weed by smothering, as suggested in the paragraph on ground elder. The foliage can be killed with Diquat and, by repeated applications, this may constitute the best means of control.

Speedwell.—*See* Veronica.

Veronica.—This procumbent, blue-flowered weed of turf is sometimes know as speedwell. Being resistant to hormones, its control may only be established with lawn sand. *See also* Lawns.

Woody Plants.—With or without the addition of 2,4-D, these may be killed with 2,4,5-T. This hormone is particularly useful on bramble, gorse, ivy, and other unwanted shrubby plants. It is necessary to thoroughly saturate the foliage of deciduous trees, and the best results are obtainable when the leaves are fully mature but not starting to die off. In the case of ivy, the dormant shoots should be generously sprayed for the best results.

Yarrow.—A weed found in many lawns where its presence often signifies low fertility. Control is with lawn sand. *See* Lawns (T32).

Summary.—From these notes it will be seen that there are many aids for dealing with weeds. The salient point is to get the *right* method for *each* plant. Equally important is to check the reason why certain weeds grow profusely under some conditions. Very often this natural tendency can be counteracted as in the case of phosphatic fertilisers against moss and in the application of organic manures and chemical fertilizers where horsetail and yarrow are concerned. *See* T35.

HORTICULTURAL SOCIETIES.

There are many specialist societies in Britain. Detailed information on particular plants is normally available from them, and membership is open to all wishing to join. The most prominent societies are:

Alpine Garden Society
Sec. Michael Upward, 58 Denison House, 296 Vauxhall Bridge Road, S.W.1.

Auricula and Primula Society, The National
Sec. A. Marlow, 52 Epsom Lane North, Epsom, Surrey.

Begonia Society, The National Society of England and Wales
Sec. F. J. Martin, 50 Woodlands Farm Road, Erdington, Birmingham 24.

Cactus and Succulent Society of Great Britain
Sec. K. H. Walden, 152 Ardgowan Road, Catford, S.E.6.

Camellia Society, The International
Sec. Charles E. Puddle, V.M.H., Bodnar
Tal-y-Cafn, Denbighshire.

Carnation Society, The British National
Sec. E. G. Cook, 1 Evelyn Rd., Worthi
Sussex.

Chrysanthemum Society, The National
Sec. S. G. Gosling, 65 St. Margaret's Avenu
Whetstone, N.20.

Daffodil Society
Sec. D. J. Pearce, College of Ascension, Sel
Oak, Birmingham, 29.

Dahlia Society, The National
Sec. H. F. Newson, 93 Byng Road, Hi
Barnet, Herts.

Delphinium Society, The
Sec. C. J. H. Topping, B.A., Ph.D., 5 Pa
Lane, Sevenoaks, Kent.

Floral Arrangement Societies of Great Brita
National Association of
Sec. Mrs. F. C. Dobson, 21A Denbigh Stre
London, S.W.1.

Floral Decoration Society, The London
Sec. Mrs. C. Heaven, 22 St. Luke's Me
London, W.11.

Fuchsia Society, The British
Sec. W. G. Sharp, Rydal, The Green,
Bentley, Colchester, Essex.

Gladiolus Society, The British
Sec. J. G. Lord, 25 Kimpton Avenue, Bre
wood, Essex.

Hardy Plant Society
Sec. Miss B. White, 10 St. Barnabas R
Emmer Green, Reading, Berks.

Heather Society, The
Sec. Mrs. C. I. MacLeod, Yew Trees, Horl
Row, Horley, Surrey.

Iris Society, The British
Sec. Mrs. E. G. Osborn, 114 Ellison Roa
Streatham, S.W.16.

Pansy and Viola Society, The North of England
Sec. F. C. Marshland, 2 Jubilee Mount, W
Lillands, Brighouse, Yorks.

Pansy and Viola Society, The Scottish
Sec. Hugh Campbell, O.B.E., 960 Dumbart
Road, Dalmuir, Glasgow.

Pelargonium and Geranium Society, The British
Sec. Miss E. D. James, 22 Lanercost R
London, S.W.2.

Pteridological Society, The British
Sec. J. W. Dyle, 46 Sedley Rise, Loughto
Essex.

Rose Society, The Royal National
Sec. L. G. Turner, Chiswell Green Lane,
Albans, Herts.

Royal Horticultural Society
Sec. John Hamer, M.B.E., B.A., Roy
Horticultural Society's Offices, Vince
Square, S.W.1.

Royal Caledonian Horticultural Society
Sec. John Turnbull, D.S.O., D.F.C., C.
Royal Caledonian Horticultural Society,
Melville Street, Edinburgh 3.

Saintpaulia and Houseplant Society
Sec. The Secretary, 54 Queensborough Terra
London, W.2.

Scottish Rock Garden Club
Sec. Sqdn-Ldr. J. J. Boyd-Harvey, Boons
Dirleton, East Lothian.

Sweet Pea Society, The National
Sec. R. J. Huntley, 431 Wokingham Ro
Earley, Reading, Berks.

FINDING LIST FOR WEEDKILLERS

ll the herbicides in this list are first-class chemicals which have been approved by the Ministry of Agriculture and available in small packs designed for use by amateur gardeners. In case of difficulty in obtaining any of them, the ufacturers should be contacted.

he list may appear unnecessarily long but the pipe dream of multipurpose herbicides is not a reality and the full ent and value of chemical weed controls are only obtained by using herbicides for their specific purposes; as such, y constitute an efficient and economic method of eradicating unwanted plants of all sorts.

ade names	Chemicals	Manufacturers	Type of action	Plants controlled	Notes and precautions
WEED KILLERS FOR USE ON TURF					
ugges 2,4-D " icotox " hell Weed- ill "	2,4-D	Bugges Insecticides Ltd., London Rd., Sittingbourne, Kent. May and Baker Ltd., Dagenham, Essex Shell Chemical Co. Ltd., 15–17 Gt. Marlborough St., W.1.	Hormone growth regulator translocated throughout the plant.	Many broad-leafed weeds and some perennial ones. Best hormone type for killing daisies, dandelions and plantains.	Primarily for use on lawns Beware of drift.
ugges .C.P.A." eed-a-Lawn" nd "Spot" n powder orm)	M.C.P.A.	Bugges Insecticides Ltd., London Rd., Sittingbourne, Kent. Pan Britannia Industries Ltd., Britannia House, Waltham Cross, Herts.	Hormone growth regulator translocated throughout the plant.	Many broad-leafed weeds and some perennial ones. Best hormone type for killing creeping buttercup. Useful against pearlwort with repeated applications.	Primarily for use on lawns Beware of drift; on small areas the powdered formulation in puffer pack can be used.
ovotox " wn Clover iller"	Mecoprop	May and Baker Ltd., Dagenham, Essex. Pan Britannia Industries Ltd., Britannia House, Waltham Cross, Herts.	Hormone growth regulator translocated throughout the plant.	Best control for white-flowered clover, chickweeds and field woodrush. Useful against pearlwort with repeated applications.	Primarily for use on lawns Beware of drift.
n sand lves Lawn and" l Calomel ust"	*See* T32(2).	Usually home made. Pan Britannia Industries Ltd., Britannia House. Waltham Cross, Herts.	Scorching of annual growth. Of herbicidal and manurial value, in most cases.	Invaluable against weeds resistant or semi-resistant to hormones, like pearlwort, moss, veronica (speedwell), yellow-flowered clover, and yarrow.	*See* Lawns (T32(2)) for detailed information. The use of calomel dusts should be confined to mosses; of no manurial value.
WEEDKILLERS FOR GARDEN USE					
ova Soil eriliser "	Cresylic Acid	The Murphy Chemical Co. Ltd., Wheathampstead, St. Albans, Herts.	Contact herbicide.	For destruction of growth of annual weeds and top growth of perennials.	Particularly valuable on asparagus beds and where annual weeds have to be controlled. Also used as a soil sterilant.
ugges alapon "	Dalapon	Bugges Insecticides Ltd., London Rd., Sittingbourne, Kent.	Translocated throughout the plant, killing vegetation by movement from leaves to roots.	Annual grasses, couch grass, sedges, reeds, and bulrushes.	Delay planting for 40 days after application. May be used, upon makers' instructions as a *selective* herbicide on asparagus, shrubberies, fruit gardens, etc.
eedol "	Diquat Salt	Plant Protection Ltd., Yalding, Kent.	Translocated throughout the plant but with scorching effect similar to contact herbicides.	Kills annual weeds and top growth of perennials. One of the few herbicides to give a good control of ground elder. Selective only by application, *i.e.*, kills all foliage it contacts.	Undoubtedly one of the most valuable and interesting herbicides to be introduced. Inactivated upon contact with soil; no residual effects. Available in small packs. Can be stored from season to season.
eedex "	Simazine	Fisons Horticultural Ltd., Harvest House, Felixstowe, Suffolk.	Soil acting, killing seedling vegetation by uptake through roots.	Controls germinating seeds of many weeds over a long period.	Apply when ground is wet in early spring on asparagus, apples, pears (not plums), soft fruit, ornamental trees, and shrubs including roses. Slow acting.
lybor- lorate "	Sodium Chlorate	Borax Consolidated Ltd., Borax House, Carlisle Place, S.W.1.	Translocated throughout the plant and soil acting.	Toxic in varying degrees to all plants except mosses. The best chemical for killing tree stumps.	To a large extent superseded by other chemicals. Can be used on paths, drives, and vacant ground.
ots Bram- , Brush- od and ttle Killer"	2,4,5-T	Boots Pure Drug Co. Ltd., Station Street, Nottingham.	Hormone growth regulator translocated throughout the plant.	Special value in control of woody plants like brambles, brushwood, and ivy. Also good against nettles.	Beware of drift.

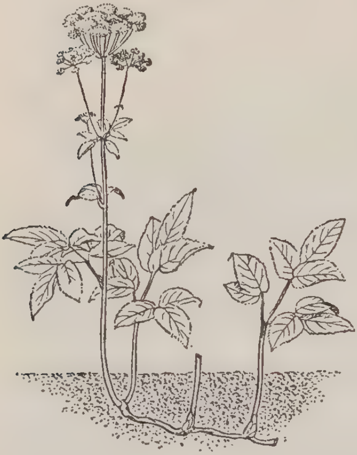
THE GARDEN CALENDAR.

January.—All digging should be finished this month. As the work is done, so generous applications of organic matter such as peat, compost, sewage sludge, leaf mould, animal manure, or a mixture of any of them, should be incorporated into the ground. On clay soils the physical condition can be improved by raking into the surface dressings of rough materials like screened ashes, road grit, or coarse sand.

Fork over ground between rows of fruit trees and in shrubberies and bury annual weeds; if land is not free of weeds in January it is unlikely to be so throughout the year.

A trench for runner beans can be made, the bottom forked over, a thick dressing of compost or kitchen waste added, and the soil replaced.

Rhubarb will require protection with compost or straw and early growth forced by covering with small tubs.



Ground Elder—A pernicious weed of neglected land. Eradicated by hand-forking early in the year or by chemicals (*see* **T33**).

Pruning of orchard trees and fruit bushes should be completed. When bird damage is severe gooseberries can be left until bud burst.

Autumn-planted shrubs and trees should be checked over, and any which have worked loose through the action of frost or wind should be firmed by thoroughly stamping over the soil.

February.—Broad beans can be sown if conditions are favourable and shallots planted by pressing the bulbs into the soil until only the tips show.

Jerusalem artichokes are an unusual crop well worth growing; plant tubers as early as possible to give a long season for maturity.

Parsnips should be lifted to check new growth and stored on the north side of a wall or fence.

“ Seed ” potatoes can be arranged in boxes and kept in a frost-proof shed; a light, airy position will encourage short, sturdy shoots.

Protective covering on half-hardy shrubs, like fuchsias and mimosa, should be removed as early as possible.

Herbaceous plants which do not over winter easily, such as delphiniums and gaillardias, may be planted at the end of the month.

Turf may be laid in February so that the grass can be established before the ground starts to dry out in the spring. Before laying, rake in dressing of “ National Growmore ” at 1½ oz. pe sq. yd. to encourage root action.

Vines under glass should still be kept as *col* as possible to maintain the dormant period As the buds swell the temperature can be higher but ventilation must be increased if it reache 45° Fahrenheit.

Fuchsias grown under glass should be prune hard by cutting back all of last season's growt to within a bud or two of the old stems. Later as new growth appears, take cuttings which wi root easily in sand under a plastic bag.

Shrubby plants like the india-rubber plan and most pot plants grown indoors or unde glass should be repotted or top dressed wit fresh potting compost.

Early strawberries can be obtained by cloching rows at the beginning of the month.

March.—Sow round-seeded spinach and broa beans for a succession in cropping.

Brussels sprouts, cabbage, lettuce, leek onions, parsley, parsnips, peas, and radis should all be sown as the soil gradually warm up

Asparagus is easily raised from seed sow this month. Sow the seeds individually 1 in apart and mark the rows by sowing a pinch o two of radish seed at intervals, as the asparagu is slow to germinate.

Onion sets can be planted as early as possibl on well-manured ground.

Spring cabbage will respond in the spring t an application of nitrate of soda at 1 oz. pe sq. yd.

Tomato seed may be sown in a warm greenhouse at the end of the month. It is a mistak to sow early in the year, as then seedlings ge drawn and weak before it is time for plantin outdoors.

Seed of half-hardy annuals, such as antirrhinums, China asters and *Phlox drummondii* may all be sown in a greenhouse or frame Remember the seed should only be covered wit a sugaring of fine soil sufficient to “ anchor the seedlings and to sow thinly.

Hedges, and particularly evergreen sort which have outgrown their stations, should b cut back, and this is the *best* month for doin so. Often drastic reduction is necessary, an such treatment will save endless, unnecessar work in trimming later on in the year. As a example, privet may be safely reduced to width of 9 in. and a height of 4–5 ft.

Evergreen shrubs, like some daphnes, rhododendrons, and hollies, may be planted and—what is most important—kept moist unt growing freely.

Over-grown lavender may be reduced in siz by cutting back into old wood.

Lawns should be fed with fertilisers to encourage new, strong growth when the turf i damp.

As buds burst on roses, so pruning and manuring can be started.

Planting time for all fruit trees is nearly ove and should be completed without delay.

As buds burst on early planted raspberrie so the already shortened canes can be cut dow to just above the lowest bud in growth; a further growth develops so the old stems ca be shortened further until, finally, cut to groun level.

April.—Potato planting for an early crop is don this month using well-sprouted “ seed.” Protect from late frosts by covering the first shoot with earth and, if necessary, applying a coatin of straw or sacking.

Onions raised under glass in boxes can be lanted outdoors.

Watch for germination of asparagus seed; s the fern-like growths appear, hand weed the ows with great care and thin seedlings to 2–3 in. part.

Hardy annuals can be sown outdoors when oil conditions are right; lightly cover and rotect from birds. Half-hardy sorts must be rown-on in frames.

New stocks of carnations, chrysanthemums, nd violas may be planted outdoors.

Transplant autumn-raised sweet peas to open arden early in the month.

Lawns may be sown as the soil warms up, nd a good surface tilth can be obtained by aking; *prior* to sowing, make arrangements to rotect the seed bed from birds by use of pea icks, wire netting, strips of newspaper dipped to lime-wash, or "Glitterbangs" or a comination of these scarers.

Evergreen shrubs, like bamboos, hollies, and hododendrons, should be planted and kept oist until well established.

Gladioli and montbretias can be planted in nny positions where soil is in good heart.

Prune winter-flowering shrubs, such as winter smine and forsythia, by cutting off the old owering stems.

Weeds will be appearing on garden paths and ives; establish an early and efficient control watering with "Weedex."

Early planted fruit trees should be mulched ith organic matter to conserve moisture in the il.

.—Brussels sprouts should be planted early the month and also late potatoes. Watch out r blackfly on broad beans, as the first infestaons are the important ones to deal with romptly.

Encourage growth on leafy vegetables, like ttuce and spinach, by a dressing of nitrate of da at 1 oz. per sq. yd.

Towards the end of month plant out tomatoes, in the first week if cloches are available.

Sow sweet corn and vegetable marrows in e open. Bedding plants and half-hardy nuals may all be planted outdoors.

Roses should be checked over for first signs greenfly infestation; spray with nicotine if cessary.

Garden pools in need of cleaning should be alt with thoroughly. At the same time water ies may be lifted and divided when growth in e previous year was excessive.

Delphiniums now develop rapidly; for best sults cut out thin shoots to leave five to seven rong growths to each plant. Stake and tie ch one and encourage healthy growth by eding with liquid animal manure or soot water one or two occasions.

Faded blooms on azaleas, lilacs, and rhodondrons should be removed.

Agapanthuses and hydrangeas grown in tubs n be brought into a sunny position. If potting has not been necessary remove top in. of soil and replace with fresh compost. ncourage new growth with applications of uid animal manure.

Window boxes should be repaired, filled with sh compost, and replanted. Remember a nerous layer of peat or leaf soil placed in the ttom will do much to conserve moisture.

Lawns will need attention, and broad-leaved eds can be eliminated by treatment with rmone weed-killers.

Small greenhouses are liable to get very hot and plants suffer accordingly especially if short of water; therefore keep staging and floors well damped. Conversely, sharp falls in temperature may be experienced and every day the ventilators should be shut down in the late afternoon in order to conserve the heat from the sun.

June.—Plant cabbages, cauliflower, celery, marrows, and tomatoes.

Sow seed of garden swedes.

After thinning beet, carrots, onions, and parsnips, feed with nitrate of soda at ½ oz. per yd. run.

Asparagus raised from seed must be kept clear of weeds and watered thoroughly at the least sign of being dry. Beds cropping in their third season should not be cut after June 1st; on old beds cutting may continue until the third week of June.

Sweet corn should be thinned and a surface dressing of compost applied.

Aubrietas now past their best should be clipped back hard to the old stems, with a pair of shears.

Seed of delphiniums, hollyhocks, lupins, and wallflowers may be sown.

Phloxes, especially if grown on light soil, should be mulched with compost and watered when necessary.

Herbaceous plants of all sorts respond to feeding if growth is below par; individual species may be fed with soot water or large beds given an application of sulphate of ammonia at 1 oz. per sq. yd., taking care to keep the crystals off the foliage of plants.

Old flower-heads on roses should be removed regularly by cutting back old flowering stems to within 4 or 5 in. of the mature wood.

Raspberries and similar berries should be mulched with compost or old manure to encourage new growth.

Strawberries may be layered if the stock is healthy and growth vigorous.

July.—Plant winter cabbage, leeks, sprouting broccoli, and kales as ground becomes available.

Sow prickly spinach and turnips for autumn and winter use.

Water celery, marrows, and runner beans at first sign of dryness. If setting is poor, beans should be sprayed vigorously with water from a hose.

Shallots may be lifted and dried off as foliage gradually yellows.

Carnations may be layered as sturdy young shoots develop; remove sufficient leaves to make a horizontal cut up the stem passing through a joint, and peg down.

Flag irises can be lifted and divided as flowering finishes. After replanting, the tubers should be showing above ground but, nevertheless, firmly in the soil.

Wallflowers may be lined out in nursery rows. To avoid sappy, lush growth do not plant on rich soil. Where ground is acid water plants with lime-water (a large handful to a gallon).

Hydrangeas can be easily propagated in July by cuttings of short flowerless shoots. These should be inserted in pots in a sandy compost and kept under a plastic bag or hand light until rooted.

Transplant into nursery rows, seedlings of biennials and perennials sown earlier in the year.

Order supplies of daffodils, hyacinths, and other bulbous plants for delivering in September. Stocks in good trade houses are often soon exhausted.

Late in the month hedges of beech, holly, hornbeam, and yew can be clipped.

August.—Runner beans are now in full bearing, and the pods should be gathered while still young, to encourage further croppings; often beans are picked much too old. Water and feed with nitro-chalk at 2 oz. per yd. run if necessary. If properly grown this is one of the most profitable of *all* crops.

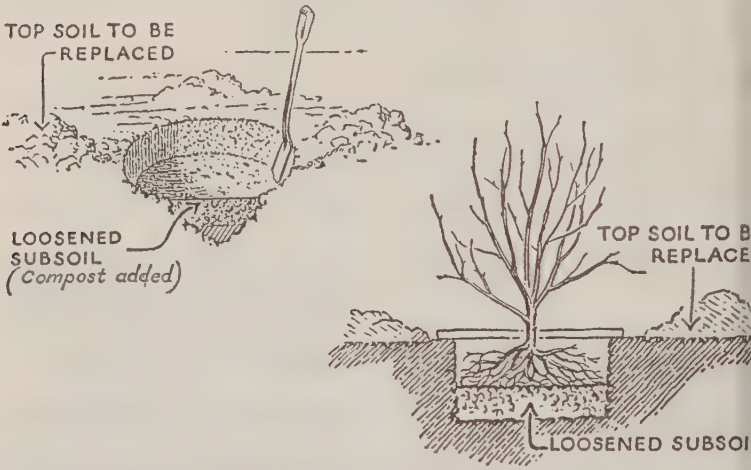
Marrows should also be gathered while still young and fresh; early development of seeds checks fruiting.

Strawberries layered in pots earlier in t year may be planted when the soil conditio are right. Use a well-manured site and pla at approved distances.

Raspberries and loganberries will now ha finished cropping, and all the old fruiting ca may be cut out at ground level.

September.—Tomatoes can be gathered while s green and ripened easily and quickly by stori in open boxes, out of the direct sun, in a wa kitchen. Such a practice is better than putti the fruit in a dark, airless cupboard.

Ground recently cleared of onions and po toes is admirable for planting out cabbages spring cutting. Apart from removing a weeds, no preparation is desirable.



CORRECTLY PLANTED SHRUB, showing planting hole and bush in position. The loosened sub- must be firmed prior to planting, and any tree or shrub must never be planted deeper tha was in its previous position or nursery row.

Seed of prickly spinach—a valuable winter crop—may be sown. As seedlings develop, thin out and on acid soils apply lime-water.

Tomatoes should be sprayed with "Bouisol" at fortnightly intervals to prevent potato blight.

Winter greens, if not already planted, should be put in as soon as possible.

Pelargoniums ("Geraniums") should be propagated by cuttings taken throughout the month as young, short side-shoots develop. Rooting soon starts if the cuttings are inserted in sand or a mixture of sand and peat.

Border carnations may be layered; encourage rooting by not allowing the plants to suffer from a lack of water.

Madonna lilies may be planted this month in an open position where they will not be disturbed.

Flowering shrubs of a wide range may be propagated in August. Short side-shoots of the current season's growth should be taken off with a heel when the wood is still young but starting to harden at the base. Insert in sand and cover with a plastic bag.

Grass seed is best sown this month whenever the soil is moist but not wet, as in the notes for April. Before sowing, any perennial weeds must be removed by hand forking.

Brussel sprouts are heavy feeders and gro should be encouraged by an application of ni chalk at 1 oz. per sq. yd. early in the month.

Carnation layers will now be rooted and young plants may be severed from the pare and transferred to their flowering positions.

Crocuses, daffodils, and snowdrops are o planted too late; September is the time for job. Similarly, these, together with hyacin may all be planted in bowls for indoor dec tion before the end of the month.

Lavender bushes can be trimmed when flowers fade; do not, however, trim or cut b in any way the old stems or foliage.

Grass seed not sown last month should be in without delay.

Roses of nearly every sort can be propaga by inserting cuttings 8–10 in. long in a sha trench outdoors. A sprinkling of sand sh be put in the bottom of the trench and the tings firmed well.

Brown rot is often prevalent on fruit. T is no remedy for the disease, and brown, ro fruit on apple and other trees should be pic off and burnt.

October.—Jerusalem artichokes are safe lef the ground, but the stems should be cut do a regular supply is wanted, then a store of bers may be lifted to ensure against hard ost.

Parsnips may, similarly, be left in the ground ntil needed.

Asparagus stems should be cut down before e seeds drop. If "fern" is cut during the mmer for indoor decoration, subsequent opping is affected.

Lettuce for early cutting next spring should e sown, late in the month, under cloches.

Virgin ground which is to be taken into ltivation should be dug as soon as possible in der that it may be exposed to a *full* season of inter frosts. There is no doubt that the maxi-um value in digging virgin land can only be ad if the work is completed well before Christ-as.

Evergreen shrubs should be planted before the eather turns severely cold.

Lily-of-the-valley will respond to a top dress-g of old animal manure or an application of one meal at 2 oz. per sq. yd. followed by a ulch of leaf soil.

Clematis grown in pots may be planted in eir permanent positions.

Lilies of various sorts can be planted early in e month.

Gladioli should be lifted, cleaned, and stored a dry, frost-proof shed.

Polyanthuses and all sorts of primroses may e planted in moist, rich soil for flowering in the ring.

Sweet Williams and pansies may be trans-rred from nursery rows to their flowering sitions.

Wallflowers should be planted without delay, ming the plants well. Forget-me-nots and ffodils may be used in conjunction with them d planted at the same time.

Most plants grown indoors have been watered eely during the summer; from now on care ust be taken in applying water, as soil only ies out slowly in winter, and growth has rtually stopped.

Bulbs in bowls must be kept as cold as pos-ble, and up to early November not more than out ½ in. of growth should be showing. amp the peat as it shows signs of drying out.

Black and red currants and gooseberries may be propagated by cuttings.

mber.—Runner beans can be cleared and the ulms used for compost; the old roots can be t in the ground and later dug-in. If the sticks e pulled up early and stored they will last for me years.

Broad beans may be sown outdoors in dis-cts where they are known to succeed; an owance for losses should be made by sowing n. apart.

Asparagus responds well to a top dressing of imal manure or compost; if supplies are short, n to apply once in three years.

Lettuce sown last month under cloches can transplanted and, under wide barn cloches, ree rows can be grown easily for cutting in e spring. Slugs may cause serious losses, water with "Slugit" at planting time and ep a few spare seedlings to fill any gaps.

Tulips may be planted throughout November.

Heaths and heathers of all sorts can be nted in peaty soils. Large clumps may be it up and replanted.

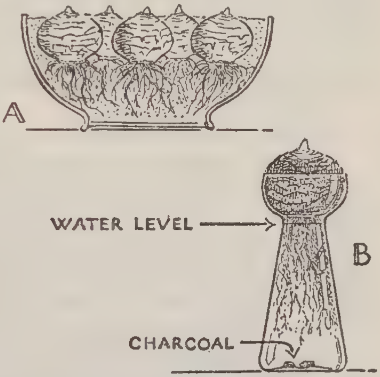
Roses and all deciduous shrubs and trees, cluding fruit trees of all sorts, should be planted as soon as possible. Always firm the soil well, but do not plant too deeply.

Where necessary, herbaceous borders can be replanted. Large clumps of perennials can be split up and the strong pieces from outside of the clump replanted; the centre of the clump should be discarded.

Continue to keep indoor bulbs as cold as possible. By the second week in November, growth should be about an inch high. Towards the end of the month, transfer to a cool, light position.

Throughout the winter continue digging and incorporating organic matter like compost, spent hops, and coffee grounds.

Vines grown in a cold greenhouse should be given full ventilation night and day. After leaf fall cut back annual growth to one bud.



Bulbs Indoors—Note strong root development before leaves appear. This factor can only be brought about by early planting (*see* September notes). In both bowl (A) and glass (B) a little bonfire charcoal is necessary for healthy growth.

December.—Decaying leaves on winter greens should be removed to give free circulation of air around the plants.

Bird damage may be prevalent on spring cabbages because of pigeons. In serious cases it is worthwhile to erect fish netting.

When frost makes cultivations impossible, pruning of fruit trees should be done. The only exception may be red currants and gooseberries, because in districts where bird damage is serious any pruning is best left until the spring.

Deciduous hedges of beech, hawthorn, and the like can all be cut back hard where the plants have got out of hand, with a view to reducing work of trimming during the growing season.

Well-berried holly is always in demand, and a variety of regular fruiting habit to fulfil the requirement is *Ilex aquifolium* 'Pyramidalis.'

For those wanting mistletoe, the seed should be planted on apple trees in the spring—not in December.

Early in the month, hyacinths can be brought into full light and warmth for Christmas flowering. If growth is a little stunted cover plants with a sheet of newspaper and give more warmth; if growth is poor look to the cultivator not the supplier.

Christmas trees to be brought indoors in pots should be thoroughly watered first, to check the needles falling through lack of moisture in hot, stuffy rooms.

CARE OF INDOOR PLANTS

Cultural Conditions.—Ideally, the temperature should be kept as constant as possible, and in cold weather plants grown in window-boxes are best moved nightly into the centre of the room to avoid damage by frost. Linked with temperature is the question of humidity, for plants respond well to a moist atmosphere. Pots may be stood on a layer of gravel which can be kept damp without allowing water to seep through the bottom of the pot and thereby saturating the soil. Gas fumes and draughts must be avoided. Plants with large leaves should be sponged regularly with soapy water. Others, with hairy leaves, like saintpaulia, may be gently sprayed, but the water must not be allowed to remain on the foliage, as it may lead to scorching or rotting.

Of all cultural practices, the most important is watering. As a general guide, plants may become *nearly* dry before watering and then be given a *thorough* soak by standing the pots up to their rims in a bucket of water. For all plants, rain-water is best; if tap water has to be used, it should reach the same temperature as that of the room before being applied.

Soils and Potting.—The important factor is to get the correct compost. This may vary slightly, but an all-round mixture can be made up of:

7 parts by loose bulk medium loam
3 parts by loose bulk granulated peat (or leaf soil)
2 parts by loose bulk coarse, gritty sand

This mixture is the basis of John Innes Potting Compost and, with fertilisers added, can be purchased in small quantities from horticultural sundriesmen. If fertilisers are not added, plants should be fed during the growing season at about fortnightly intervals (depending on the particular plant) with a dilute solution of liquid animal manure; alternatively, 2 oz. of the following mixture dissolved in a gallon of rain-water can be used:

5 parts by weight of sulphate of ammonia
7 parts by weight of superphosphate
2 parts by weight of sulphate of potash

Normally a plant will grow satisfactorily in the same soil for three or four years. After this annual growth may be poor together with yellowing or dropping of the foliage. The plant is then in immediate need of repotting. To do this a large crock should be put into the bottom of the new pot—which should be generally a shade larger—followed by a little compost. Then the matted roots of the plant can be teased out with a pointed stick, put in the pot and more compost worked firmly around the roots. When repotting is not absolutely necessary, the top inch of soil can be taken off annually and the pot top-dressed with fresh compost. Both repotting and top-dressing are best done before growth starts in the spring.

Florists' Plants.—Plants like cyclamen and cinerarias, which are purchased in flower and usually discarded when flowering has finished, are forced for seasonal trade in the moist atmosphere of a heated greenhouse, so do not respond kindly to treatment indoors. One of the loveliest of these plants in *Azalea indica*, the Indian or evergreen azalea. After flowering it can be kept in a cool greenhouse. It needs plenty of moisture, and as it is a calcifuge, only rain-water can be used. To encourage growth after flowering, spray the foliage regularly and apply dilute, liquid animal manure or dilute soot water. Cyclamen is difficult to grow really well, and cultural notes should be followed. With expert attention old plants can be flowered for ten years or more, although the best results are obtained from one-year seedlings. On the other hand, varieties of cineraria are grown as biennials. These need cool, airy conditions, and should be watered freely but, at the same time, with care not to over-water.

At Christmas-time numerous varieties of primula will be offered for sale. All of them are of comparatively easy culture, and if top-dressed and fed can be grown-on for a year or two. Some varieties, particularly those of *Primula obconica*, can cause a rash on those susceptible to it. Other plants which can be kept after flowering are the varieties of *Solanum capsicastrum*, the wint cherry.

Indoor Plants.—The ones listed are among tho which can be grown as permanent features most homes if given reasonable care.

Begonia.—An enormous genus of plants world-wide distribution, many being suitable f indoor cultivation. Of particular interest are *heracleifolia* and *B. manicata*, both being easy propagate from cuttings under a tumbler.

Billbergia nutans.—This is a member of t pineapple family, the Bromeliads, having typical narrow, spiny-edged leaves. Nearly hardy, a will flower in a warm room. Do not repot unle absolutely necessary, as the roots are best co fined.

Campanula isophylla (Harebell).—A charmi blue-flowered plant with a long flowering peri Easily grown in cool conditions, and its pendulo habit makes it useful for a basket. After flow ing, remove dead flower-heads and trim strag shoots. There is a good white form, 'Alba.'

Cacti.—Innumerable sorts are used as hou plants. In the main, all should be grown in sandy, gritty soil with sharp drainage; wat may be given freely in the summer, but withhe in winter, except to prevent the soil drying o Two cacti which will flower freely and are p ticularly worthy of cultivation are *Aporocact flagelliformis*, the rat's tail cactus, and *Epiphyll ackermanii*. Both are tolerant of poor conditio and neglect. Mention should also be made of t old-fashioned Christmas cactus, *Schlumberge bridgesii*, as a great favourite, but an infinite more exciting one of a similar type is the r *Rhipsalidopsis gaertneri* with bright-red flowe

Crassula.—Shrubby members of this gen make fine house plants, growing well in light soil full sun. Particularly valuable are *C. lactea* which has white flowers annually and lar succulent, spoon-shaped foliage—and *C. falcata* choice plant with red and yellow flowers.

Ivy.—Common in many continental houses, ivies show an interesting range of colour, sha and size in their foliage. Invaluable as climbi plants and in warm rooms, the Canary Island i is worth trying. A related plant raised in Fra is *Fatshedera lizei*. All of these prefer a dam leafy soil, and the foliage should be spray occasionally.

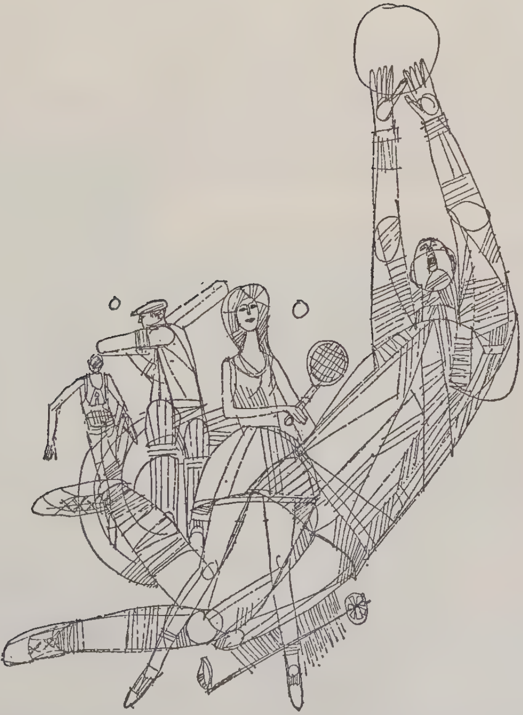
Monstera deliciosa.—A striking plant w large, deeply-cut leaves and long, thick, aer roots, many of which do not reach the grou Often seen as a prominent decorative feature continental homes. Requires a leafy soil a generous watering. Spray or sponge foli regularly and avoid fluctuation of temperature its cultivation.

Pelargonium (Geranium).—Ease of cultivati and beauty are found in this plant and its infin varieties. Some of these, like 'Mrs. Cox,' h multi-coloured leaves and are well worth hunti for in trade lists. During the summer f generously and keep the stock vigorous by rooti cuttings annually in the late summer.

Philodendron.—Most climbing plants w aerial roots and represented by a number species from tropical America. Fairly tolerant adverse conditions, but dislike draughts a require light shade, free watering, and a r open soil. *P. scandens*, with heart-shaped leav is typical of the climbing group; *P. bipinnatifid* with broad, incised leaves, of the non-climbers.

Saintpaulia (African violet).—A charmi dwarf plant with hairy leaves and pretty sin and double flowers in many colours. It is *difficult* plant to grow well, as it thrives in a stea temperature of 65–70° F. and a wet atmosphe Water from below. Rotting of leaves is due excess of moisture, draughts, cold, or gas fume

GAMES & RECREATIONS



GAMES AND RECREATIONS

PEOPLE have always been fond of playing games and of thinking out ways of spending their leisure ti and of celebrating special occasions. The result is a long history of games, recreations, and custo some of which are described in this section. The arrangement is alphabetical.

One problem that confronts those keen to try some game or recreation is how to set about it. many cases, the simplest way of finding out what facilities exist in a particular area is to enquire a local newspaper office, which will have particulars of all sports clubs, dramatic societies, and ot recreational bodies in the area. A few addresses that might be useful to those with certain speciali interests appear at the appropriate places in the text, and a valuable source of helpful information many games and recreations is the Central Council of Physical Recreation, which has English, Scotti Welsh, and Northern Irish addresses as follows: England, 6 Bedford Square, London, W.C.1; Sc land, 4 Queensferry Street, Edinburgh, 2; Wales, 18 Windsor Place, Cardiff; and Northern Irela 45 Arthur Street, Belfast. Those keen on touring the country at moderate cost might appreciate services provided by the Youth Hostels Association, which has addresses as follows: England a Wales, Trevelyan House, St. Albans, Herts, with a London office at 29 John Adam Street, W.C Scotland, 7 Bruntsfield Crescent, Edinburgh, 10; Northern Ireland, 28 Bedford Street, Belfast; a the Irish Republic, 39 Mountjoy Square, Dublin.

American Football.

American Football is played eleven-aside on a pitch marked by a line across it every 5 yards, and with goals and a ball resembling those used in Rugby Football (*q.v.*), though the ball is smaller. Scoring is by "touchdowns," which are like Rugby tries, but count six; goals after touchdowns, which count one; field goals during play, which count three; and "safeties," which give the attacking side two points if the defenders carry the ball over their own goal-line and touch it down. The ball is advanced by carrying it, forward passing, and kicking. The game consists of a series of "plays" or "downs," the ball becoming dead when the ball-carrier is tackled. A team must advance 10 yards in four downs or give up the ball to their opponents. Players can run ahead of the ball-carrier to protect him by "blocking" opponents. Penalties take the form of distance, usually 5 or 15 yards, lost. A game lasts 60 minutes, divided into four 15-minute quarters.

Angling.

Angling, which is catching fish with rod, line, and hook, goes back to beyond the beginning of history, for it was known to the Greeks and Romans. It is now a recreation, for, though the catch may subsequently be cooked, it is not primarily fishing for the pot. It has its competitive side, with competitions offering prizes for the biggest catch, and there are angling clubs, but many people prefer to use it as a recreation to be enjoyed alone in quiet surroundings. It is actually not so much a recreation as many recreations, for fishing can take place in the sea, rivers, lakes, ponds, and even canals, and there are several entirely different kinds of angling. The most obvious divisions are fresh-water fishing, including coarse and fly-fishing, and sea angling, including fishing from piers and the shore and big-game fishing.

The biggest branch of angling is fresh-water fishing for general or "coarse" fish, which are so called to distinguish them from "game" fish like salmon. Coarse fishing is bait fishing, or, in the case of pike, spinning, groundbait also being thrown in before and during fishing. It covers many varieties of fish, and the bag may be a very mixed one. Certain fish, of course, are known to frequent certain localities or types of locality, but, though the angler may know exactly the kind of fish he is after, he rarely knows if his catch will consist entirely of that kind of fish, or even if it will include any of that kind. Coarse fish do not generally make good eating.

Fly-fishing for salmon and trout differ widely from coarse fishing, and from each other. As the name implies, artificial flies are used, but th used for trout are quite different from those t attract salmon. In the case of trout, a fly is m to resemble a real insect as closely as possible, b with salmon, this is not necessary. Saln rarely, if ever, feed in fresh water, and, when that type of water, they are usually irrita They will dart wildly at any objects that attr their attention, so salmon flies are simply bri objects designed to draw them on. Fly-fishin rather an expensive sport, for it means hi beats on private water. In both coarse and fishing the angler would be well advised to k out of sight of the quarry as much as possible.

Old though angling itself is, sea angling comparatively recent development of it, re dating back only to the nineties of the ninetee century. It is now the most competitive form angling, with sea-angling festivals and c petitions plentiful during the holiday season. with coarse fresh-water fishing, the catch can b very mixed one. Sea angling has what might called its equivalent of fly-fishing in fishing w feathers, which attract several kinds of fish.

The sea is also the scene of the greatest of forms of fishing, big-game fishing, when a si bite can mean a catch of 1000 lb., if the angler win the terrific battle to land it. Big-game f ing takes place from a motor-launch, which is towed by the hooked fish, but follows it, so t the ensuing fight is between man and fish, and between the fish and the dead weight of the b Such a fight could last for 12 hours, and it is ne certain that the angler will win it. With fis this size, some of them with a terrifying armo of razor-sharp teeth, liable to turn back on boat or leap clear of the water, big-game fish can sometimes be as dangerous as the m adventurous sportsman could wish.

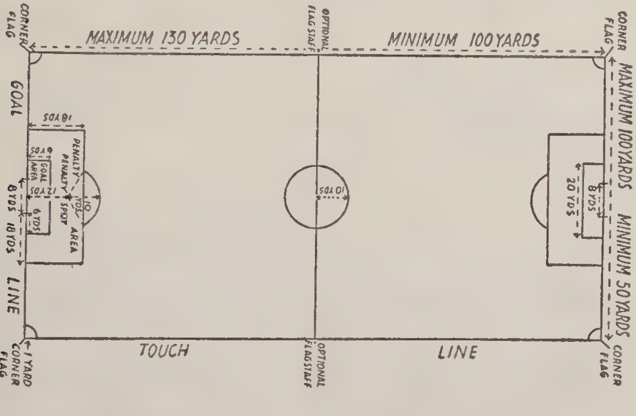
Archery. *See* Old English Games and Customs.

Association Football.

Games that may have resembled football w played by very ancient races, and games t certainly were football of a kind were playe the England of several centuries ago, but Association Football that is the most popular g in Britain, and perhaps the world, to-day ha origins in the games played at English Pu Schools in the days before sport became organi

It was not surprising that some of those had played football of one kind or anothe school should want to go on playing after t left, but, before they could do so, it was neces to work out a set of rules that would be univers understood and accepted. Meetings were or ised by those interested, and, as the univers e natural meeting-places for boys from many ols, it was there, particularly Cambridge, these took place.

was soon evident that there was a major rence of opinion between those who wanted lling permitted and those who opposed this. rival factions proved irreconcilable, so they t their separate ways. The handling enthusi- based their rules on those in force at Rugby ol, and thus pioneered Rugby Football (*q.v.*). se who felt that football should be played narily with the foot brought into being the e that was to take its name from the As- ation that was formed, in 1863, to govern it, became Association Football, often called he abbreviation, "Soccer."



occer is played with a round, leather-covered weighing from 14 to 16 ounces, and with a umference of from 27 to 28 inches, on a pitch ed out as in the accompanying diagram. It ayed eleven-aside, the positions being goal- er; right and left full-backs; right, centre, eft half-backs; and five forwards, playing at de-right, inside-right, centre-forward, inside- and outside-left. The object is to score by putting the ball between uprights rds apart and under a crossbar 8 feet high. ball is advanced by kicking or heading, but the goalkeeper when in his own penalty area handle it, and he may not carry it. A game for 90 minutes, divided into two halves.

e game is started by a kick-off from the e, with all the opposing players outside the e circle and in their own half. The ball travel at least its own circumference into the nents' half, and the kicker may not play it until someone else has done so. The right to off is decided by a toss that gives the winner ption of kicking or choosing which goal he lefend. Ends are changed at half-time, after the ball is kicked-off by the side that did o so at the start. The game is restarted in vay after each goal, the non-scorers kicking-

he ball crosses the touch-line it is thrown in player of the side that did not put it out, the being two-handed. If it crosses the goal- ide of the goal it is kicked-off by a defender the 6-yards line if the attackers were respons- and by an attacker from the intersection of oal-line and the touch-line if the defenders responsible.

ringements are penalised by free kicks, which be "direct" or "indirect." Direct free from which a goal may be scored, follow rate infringements, indirect free kicks, from a goal cannot be scored, being for more ical offences. Offences by defenders in the ty area are generally penalised by a penalty kick, which is a shot from a spot 12 yards out from the centre of the goal, with only the kicker and the goalkeeper in the penalty area, and the goalkeeper barred from moving until the ball has been kicked. However, certain offences in the penalty area, such as carrying by the goalkeeper and obstruction, are penalised only by an indirect free kick.

A player is "offside"—called "sneaking" in the school games from which the rule came—if he is nearer the opponents' goal-line than is the ball unless there are two opponents between him and the goal-line, or unless the ball was last played by an opponent. He cannot, however, be offside in his own half, from a corner kick, or from a throw-in. If a player in an offside position interferes with the game, a free kick is awarded.

A game is controlled by a referee, who has the assistance of two linesmen. These may signal infringements, but the referee is not bound to act on such signals.

In Britain, soccer is a winter game, the season lasting from August until May, though, in Scotland, it continues even during the short summer season in the form of five-aside football, known as the "short" game. British soccer is highly organised, ranging from the fully professional Football League of four divisions and the equivalent, though slightly smaller, Scottish League through minor professional leagues to amateur leagues. There are also many cup competitions, from the Football Association Challenge Cup and the Scottish Cup downwards.

The game has also spread almost all over the world, being extraordinarily popular all over Europe and in South America, and played to some extent in the United States, Canada, South Africa, Australia, and other areas. There is a World Cup competition that is played for every four years, a European Nations Cup, played for every two years, and an annual European Champion Clubs Cup competition played for by the top club of almost every European country. Soccer is also included in the Olympic Games.

Athletics.

The sport of Athletics, which includes running, walking, jumping, and throwing, is probably the most natural of all sports, and certainly one of the oldest.

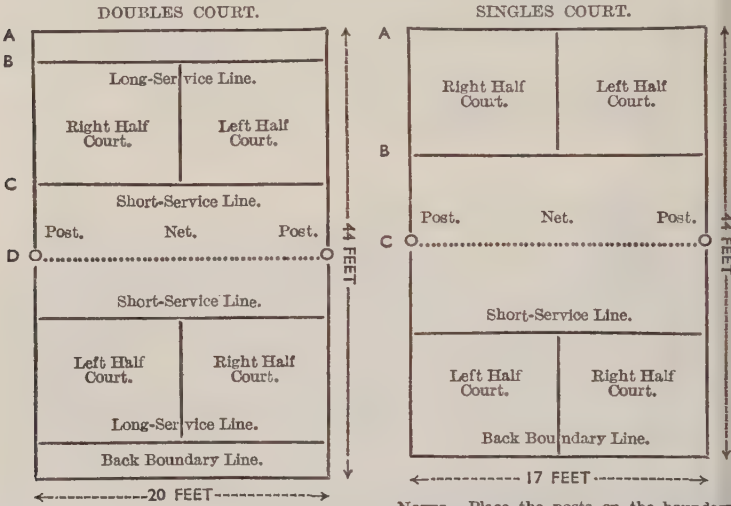
Modern Athletics can be said to have begun in 1849, when the Royal Military Academy instituted a meeting that was followed by a similar meeting at Exeter College, Oxford, and, subsequently, at other Oxford and Cambridge Colleges. The Civil Service were also early in the field; and the first athletic club was the Mincing Lane Athletic

Club, now the London Athletic Club. There was also the Amateur Athletic Club, which organised an annual championship meeting, and acted as a governing body for both athletics and amateur boxing.

In 1880 the Amateur Athletic Association was formed as a governing body. Other countries, particularly the United States, took to the sports and in 1896 the first modern Olympic Games were held at Athens. Other international meetings and matches followed, and championships and competitions of all standards were started in many countries. Women came into the sport in the early 1920s, and were included in the Olympic Games in 1928. There is now a long list of internationally agreed standard events, including distances measured in yards and miles, and also their metric equivalents; and including also a major all-round test, the ten-event Decathlon.

The longest strictly standard distances are the Marathon of 26 miles 385 yards for runners, and 50,000 metres for walkers, but there are regularly held longer events. For runners, the longest annual race is between Durban and Maritzburg, about 55 miles, the longest in Britain being from London to Brighton, about 53 miles; but there are occasional 100-mile and 24-hour events. For walkers, there are annual 100-mile races and fairly regular 24-hour ones.

The Marathon commemorates the run of the courier Pheidippides from the battlefield at Marathon to Athens, carrying the news of victory over the Persians (490 B.C.). This run covered about 25 miles but the distance was standardised at 26 miles 385 yards in the 1908 Olympic Marathon from Windsor to the White City, London. All Marathons commemorate the Battle of Marathon, but the oldest annual Marathon, the Boston Marathon, also commemorates the Battle of Lexington (the first battle of the American Revolution), and, more particularly, the ride by Paul Revere that preceded it.



NOTE.—If it is practicable place the posts on the side boundary lines; failing this, place them at any distance not more than 2 ft. outside these lines.

A to B 2 ft. 6 in. A to C 15 ft. 6 in.
A to D 22 ft.

NOTES.—Place the posts on the boundary lines or not more than 2 ft. outside these lines.

The back boundary lines become the long-service lines.

A to B 15 ft. 6 in. B to C 6 ft. 6 in.

Top of net 5 ft. from ground at centre and 5 ft. 1 in. at posts.

Diagram of Ground as marked out for Badminton.

Cross-Country. Athletics is mainly a summ sport, but in cross-country running it has extremely popular winter branch.

Cross-country originated in the traditional ru at various English Public Schools, particular Rugby and Shrewsbury; and came into wid prominence when it was adopted by the Tham Rowing Club as winter training. It is still used training by many sportsmen of all kinds, but it now also a thriving competitive sport in its ow right. There is an International Championshi but this is not yet fully representative, bei virtually confined to Western European natio Major cross-country championships are ov courses of 9 or 10 miles.

Australian Rules Football.

Australian Rules Football is played 18-aside large, oval grounds. There is no offside, scoring in goals and behinds (near misses) is hi It is played to the practical exclusion of all ot forms of football in the southern half of Austra

Badminton.

Badminton might be described as an ind version of Lawn Tennis (*q.v*) in that it is pla over a net, and can consist of either singles doubles. There, however, the resembla ceases. Only the serving side can score. If server wins the rally one point is scored; if loses the next player serves. A game is won the side first making 15 points. Three ga make a set. The shuttlecock or " bird " is a s cork hemisphere in which feathers are fixed. shots are volleys.

Bandy. *See* Skating.

Baseball.

The invention of Baseball, a summer g played from April until October, and the natio e of the United States, is generally credited to army officer, its origins being old country es called " One Old Cat " and " Two Old Cat." ams are nine-aside, and bat and field in turn. main part of the ground, the " diamond," has pase," marked by a sack, at each corner, the from sack to sack being the " base paths." base is " home," and there the batter stands, square of rubber on the ground, called the te." The base forward and to the right of a -handed batter is " first," the one straight l of him is " second," and the one forward to his left is " third," the distance from one to the next being 30 yards. 20 yards out ght in front of the plate is the pitcher's und." The lines from home to first and from to third are continued beyond these bases, are the " foul lines."

is the object of the batting side, using a bat h resembles a long, heavy Indian club with h to hit a hard, white ball weighing 5 ounces, ore runs, one being scored each time a player pletes a circuit of the bases, not necessarily one hit. When a batter leaves the plate, r " out " or to proceed along the base paths, next man comes in, the team's innings lasting three men are out. Nine such innings plete the game, and, in each innings, the ng side carries on at the point in the batting reached in the previous innings. There is oss for first innings, the visiting side always ng first.

e pitched ball reaches the batter without hing the ground, and, if not hit, it should pass the plate between the batter's shoulders and s. If it does so, it is a " strike," and three strikes dismiss the batter. If it does not, it strike only if the batter swings at it; otherit is a " ball," and four balls give the batter e passage to first base, called a " walk." tter also walks if he is hit by a pitched ball. r ways in which the batter can be dismissed y being caught, and by being " put out " on the base paths by failing to reach the to which he is running before the ball. n an out is made, the ball does not become d." If there is more than one runner on the paths, then, if the ball can be relayed quickly gh, two, or even three, men can be put out on ame " play."

he batter hits fairly, he must run, but, to be the hit must be in front of him and between oul lines. A " foul hit " counts as a strike st him, except that the third strike, which lly dismisses him, must be a clean one across late. If a foul is caught, he is out.

e fielding side is divided into three sections, battery," the " infield," and the " outfield." battery consists of the pitcher and the er, who stands behind the plate and gives ls indicating the kind of ball he thinks the er should deliver: for, though the pitched does not touch the ground, pitchers can ce a wide variety of deliveries, including us kinds of curve. The infield consists of rst baseman, at or near first; the second nan, between first and second; the shortbetween second and third; and the third nan, at or near third. The outfield covers round beyond the infield, the three remainielders taking the right, centre, and left ns of it. Catchers wear a large glove on the hrowing hand, a mask, a chest protector, leg-guards. All the other fielders wear a on the non-throwing hand, the first base- being larger than the others. The batter no protective gear.

bstitutes are permitted, pitchers frequently changed if they are being hit, and " pinch s " being sent in instead of weak batters if a desperately needed. If this happens, the replaced, often the pitcher, cannot return his side fields again, though his field replaceneed not be the man who batted for him.

with Cricket (*q.v.*) batting averages are led, these being calculated by dividing the er of times at bat into the number of hits. erage of 0·400, referred to as " four hundred," be exceptionally good. " Hits " mean safe hits on which the batter achieved one or more bases without giving a chance. If he reaches base because a catch was dropped or a ball misfielded, he plays on from there in the usual way, but is not credited with a hit. Pitchers are graded according to the number of games won and lost. Recorded fielding statistics include each man's " put outs," " assists," which are throws from which a team-mate made a put out, and " errors."

In the United States there are clubs and leagues of all standards, from professionals of various classes through semi-professionals to amateurs, called " sandlotters," and boys. The top class of all consists of two major leagues, the National and the American, each with eight clubs. The champions of these two leagues meet in a best-of-seven-games series for the " Championship of the World," always known as the World Series.

Baseball is also the chief summer game of Canada, and it is quite widely played in some other countries, including Australia, Britain, and Japan.

Softball. Similar to Baseball is Softball, which is popular in the United States with girls as well as men, and which was demonstrated in Britain during the War by American and Canadian servicemen. The ball is not particularly soft, but it is larger than a baseball, and pitching is underarm. Distances between bases, and between the plate and the mound, are shorter than in the parent game.

Basketball.

Basketball was invented by an American Y.M.C.A. official at Springfield, Massachusetts, as a winter team game that could be played indoors. It can be played in almost any gymnasium or hall, and it can also be played outdoors on an asphalt court. In America it is played by teams of all standards from schoolboys to professionals, and it is watched by more spectators than any other game. It has also spread to almost as many other countries as has Association Football (*q.v*), and it is included in the Olympic Games. It has been established for some years in Britain, where it has been encouraged by the Services and the Y.M.C.A.

Basketball is played five-aside, substitutes being permitted, with a ball resembling that used in Association Football, and goals consisting of posts that have iron rings with short nets attached to them and backboards. It is purely a handling game, and the ball is advanced by dribbling, which means bouncing, and by passing. Deliberate bodily contact is not allowed. Goals thrown during play count two points, and goals thrown from free throws after infringements one point. Height is an asset in the game, which demands stamina and agility, and which has been highly recommended as an ideal training activity by coaches of other sports, particularly Athletics (*q.v.*).

Girls also play Basketball, and, in Britain, there are national championships for clubs and schools, and international matches between England and Scotland.

Biathlon. *See* Winter Sports.

Billiards.

Billiards, which originated in France, is a game of angles, and of very great skill. It is played on a table measuring 12 feet by 6 feet 1½ inches, having six pockets, one at each corner, and one in the middle of each side. The table is covered with green baize, the edges being of cloth-covered rubber, called " cushions." Across the table, 2 feet 5 inches from the bottom edge, is a line, called the " baulk " line, the space between the line and the bottom of the table being " baulk." On the baulk side of the line there is a semi-circle with a radius of 11½ inches from the centre of the line. Down the centre of the table are four "spots," one 12¾ inches from the top, one midway between the top and the centre, one in the centre, and one in the middle of the baulk line. Two white balls, one with a spot for identification purposes, and one red one, are used, the balls being played with "cues" that taper down to a striking tip. The remaining equipment includes a long, cue-like stick with a metal cross fixed diagonally on the end, called a "rest" or "jigger," and a special long cue, these being used when the player cannot reach his ball in the ordinary way. Most games are "singles," though "doubles" can be played, the object of the game being to score points according to fixed rules, an agreed number of points making the game.

To decide who is to start, players "string" by playing their balls simultaneously from baulk up to the top cushion, the ball which returns nearer to the bottom cushion winning. At the start, the red ball is "spotted" on the top spot, and players start from the baulk circle. Scoring is three for pocketing, or "potting," the red or going in off the red; two for potting the white, which is, of course, the opponent's ball, or going in off the white; and two for a cannon, which is hitting both the other balls. A player whose shot hits no other balls at all gives one point to his opponent, unless his ball goes into a pocket, when he forfeits three. A player's turn, called a "break," continues as long as he is actually scoring. When the red is potted, it is immediately respotted.

Snooker. Also played on a billiard table, and perhaps even more popular, is Snooker, which uses 22 balls, positioned as follows: 15 reds in the form of a triangle with its apex on the second spot from the top, and its base at the top end; a black on the top spot; a pink touching the apex ball of the triangle; a blue on the centre spot; a brown in the middle of the baulk line, with a green beside it on the left end of the baulk circle, and a yellow on the right end; and a white, which is the cue-ball to be played. The points values of the balls are from one for red, through yellow, green, brown, blue, and pink, to seven for black. A player's turn continues as long as he scores, his first shot being at a red, when, if he pots one, he plays at one of the other colours, play being at reds and colours alternately as lon as balls are being potted, and as long as there are reds on the table, after which the remaining colours are played in ascending order of value.

A variation of Snooker is Snooker Plus. This uses two additional balls, an orange, placed between the pink and the blue and valued at eight points, and a purple, placed between the blue and the brown and valued at ten points.

Pool, Russian Pool, and Pyramids. Other games played on a billiard table include Pool, Russian Pool, and Pyramids. In Pool each player has a ball of a different colour, the order of play being white, red, yellow, green, brown, blue, pink, black. Each player plays at the ball of his predecessor, and tries to pot it, the game starting with white spotting his ball on the top spot, so that red is actually the first to play. A player whose ball is potted loses a life, players losing three lives dropping out of the game. A turn continues as long as a player is potting balls, and if he clears all the balls on the table he then spots his own ball for the next player.

Russian Pool uses the yellow, green, blue, and black balls, with the white as cue-ball, the black being placed on the top spot, the blue on the centre spot, the green on the left side of the baulk circle, and the yellow on the right side. A player's first shot must hit the black, after which he can play at will. Scoring is by potting balls, by going in off balls, and by cannons, but the black can be used only for the top pockets, the blue for the middle pockets, and the green and the yellow for the bottom pockets. Cannons count two, potting or going in off counting nine for the black, seven for the blue, five for the green, and three for the yellow. A player's turn continues as long as he is scoring, but consecutive cannons on the same balls are limited to 25, and the same ball must not be potted from the same spot more than three times in succession. A complete miss forfeits three points. A variation of Russian Pool a
the pink ball, which is spotted on the second s
from the top, counts six, and can be used w
any pocket.

Pyramids uses the 15 reds, starting in t
triangle, and a white cue-ball, the object bein
pot the reds. A turn continues while a playe

Boat Races.

Race rowing is a strenuous sport that make
pretence of attracting as many active particip
as some other sports and games; yet its l
history includes races with unusual stories ab
them; races that are amongst the greatest ann
international sporting events; and one race t
provides what is probably the most enthusiastic
supported free sporting spectacle in the world.

That, of course, is the Oxford and Cambri
University boat race, rowed on the Thames fr
Putney to Mortlake. First rowed in 1829,
has offered its excited public, which inclu
thousands of people with no connection of
kind with either university, everything, includ
runaway victories, dead heats, and even sink
boats. To all intents and purposes, this i
regular annual event, and has been so since 18
but, in actual fact, every race is the result o
separate special challenge from the losers of
previous race to the winners of it. The race
an interesting parallel in the United States, wh
Yale University, whose colours are dark bl
annually meet Harvard University, which is
Cambridge, on a river called the Thames.

The Oxford and Cambridge race is the be
known annual race on the Putney–Mortl
stretch of the Thames, but it is by no means
only one. There are other races that attr
entries sometimes numbered in hundreds: entr
that are far too big to race abreast on the Tham
and so race in single file, with crews follow
each other at fixed intervals in what are kno
as the Head of the River races. The bigg
of these is for crews of eight, but there are ot
Head of the River races for women's crews, w
cover only part of this famous stretch of wat
and for single scullers. Single scullers also co
this course in a straightforward race in the Wi
field Sculls event, which ranks as the Engl
Amateur Championship, and which was first h
one year after the first Oxford and Cambri
race, in 1830.

Head of the River races, but with a differen
are also held between the colleges of Oxford a
Cambridge, where the Isis and the Cam, resp
tively, are much too narrow to permit straig
forward racing. These are the Bump Races,
which each crew endeavours to catch and bu
the crew ahead of it, except for the leading cr
which can concentrate on staying in fro
When a bump is achieved, the two crews pull i
the bank, and change places for the next da
racing. The racing goes on for four days, an
is, of course, the ambition of each crew, ap
from the leaders, to register a bump on each d

Back on the Thames, but farther down it
wards the port and docks of London, is the sce
of a race that makes the Oxford and Cambri
race and the Wingfield Sculls look like rec
innovations. This is the annual race fr
London Bridge to Chelsea for the Doggett's C
and Badge, a single sculling event open only
young watermen who are within twelve months
completing their apprenticeship. It was foun
in 1715 in honour of the House of Hanov
and to commemorate the anniversary
"King George I's happy accession to the thro
of Great Britain," by Thomas Doggett, a Dubl
born actor connected with the Drury Lane a
Haymarket theatres, who regularly travelled
the Thames in preference to using the roads, a
who left a sum of money to perpetuate the ra
which is now controlled by the Fishmonge
Company.

This race is more truly an annual one than al- st any other event; for, while most so-called nual races have been subjected to long inter- ptions because of the two World Wars, those alified for the Doggett races during those years re subsequently traced, and the races duly cided after the wars. The event is a colourful e, always followed by a barge carrying a batch past winners wearing the Coat and Badge, and o the cap, breeches, silk stockings, and buckled es that go with them. The scarlet, pleated, lted Coat, with its silver buttons and the large ver arm Badge bearing the White Horse of nover and the word " Liberty ", are presented the Fishmongers' Hall, where the winner is eted with a salute of trumpets and the tune, ee the Conquering Hero Comes."

For a rowing event of a very different kind, ting back " only " to 1839, one must go up the ames, far beyond the end of the Tideway, to nley, for the annual Royal Regatta. This nsists of events open to the world and others sed to English colleges and schools for eights, rs, pairs, double sculls, and single sculls, the st famous of its races being the Grand Challenge p for eights and the Diamond Sculls.

A journey far from the Thames will bring to light story of a rowing trophy that first appeared teen years before Oxford first met Cambridge. e Carrow Cup was awarded for a four-oared race the River Yare, in Norfolk, from Carrow Bridge Whitlingham and back in 1813. Sometime ring the 1840s that cup disappeared: to re- pear in 1890—in Australia. In 1947 it came o the possession of the Victoria Rowing sociation, which made it the trophy for a pair- ed race, but sent it to England for exhibition the 1948 Olympic rowing museum. There it s recognised as a Norfolk trophy, and, though eturned to Victoria, it came home again in 1950, en the Melbourne club gave it to the Norwich wing Committee, which now annually awards o " the Norwich club whose general perform- e, judged by a points system in Regattas, shall best."

vls.

Bowls, one of the oldest of all games, was once arded as " an old man's game," but it actually many devotees of all ages and both sexes, and layed indoors as well as outdoors. It certainly s back to the thirteenth century, when its ularity made it one of the games legislated inst as likely to draw people away from nery. Henry VIII played; and the famous ne on Plymouth Hoe, in which Sir John wkins stayed to beat Sir Francis Drake even r the Armada had been sighted, if not nitely authenticated, is accepted as fact by eral historians. It is interesting to note that, his game was played, it would have been al- st identical with a game of to-day, for it was hat century that the " bias " that is a leading ure of the bowls or " woods " was introduced. century later, however, Bowls, which was ely played on greens attached to taverns, uired a reputation as being merely an adjunct pot-house revelry, but it was revived on a her level in Scotland, and never again came so r to oblivion.

here are actually two games of Bowls, the k or Level Green game and the Crown Green ne, and it is the rinks rather than the objectives differ. The Level Green game is the more ely played, and it takes place on a perfectly piece of well-cared-for turf. The Crown en game, which is popular in the North and lands, is played on a green of which the centre inches or more higher than the corners. The games differ—for instance, in the putting into play of the object ball—but only slightly, so it will be appreciated that the Crown Green game demands a good deal of experience and skill. It is mainly a singles game, whereas the Level Green game is played between sides consisting of one, two, three, or four players.

Bowls looks a simple game, the object being simply to place the bowls as near as possible to the object ball, or " jack." The bowls, however, are " biased," and the game is actually one of considerable skill. When bias was introduced, it took the form of weighting with lead, but it is now achieved by turning one side of the bowl less round than the other. Level Green bowls weigh up to 3½ lb., but Crown Green bowls are smaller and less biased. On the Crown Green, however, the jack, which is played into position by the first player, is also biased.

Players normally use two bowls in a game, or four in singles, and the side with the best record of bowls near the jack wins the " end," and the best record of shots in an agreed number of ends the game.

A Bowls green is such a perfect piece of grass that it might be thought that the expression " rub of the green," used to describe an unavoidable piece of bad luck, comes from this game. In actual fact, though, it would probably be more correct to attribute this phrase to Golf (*q.v.*).

Boxing.

Boxing, sometimes called " The Noble Art of Self Defence," though actually aggression is its keynote and defence an incidental, is a modern continuation of the old sport of prize-fighting, which, though always illegal, was popular from the time of the Regency until it was succeeded by the present-day glove-fighting at the end of the nineteenth century.

In prize-fighting bare fists were used, and wrestling holds were allowed. Rounds ended when a fighter went down, and fights continued until, following a knockdown, a man failed to come up to the scratch line in 30 seconds.

In modern boxing, gloves are worn, and no wrestling is allowed. Rounds last for a fixed time, generally 3 minutes with 1 minute between rounds, and fights last only for a fixed number of rounds, never more than fifteen. A knockdown does not end a round, the man who is down having 10 seconds in which to rise. If he fails to do so, his opponent wins by a knock-out. If a man fails to come up at the beginning of a round or if the fight is stopped to save a man from further injury, the victory is by a technical knock-out. If, however, both men are still on their feet at the end of the stipulated number of rounds, a decision is given on points. Boxing is therefore technically a contest of skill for points, and, as such, far removed from prize-fights to a finish.

Fights are controlled by a referee, and, in British professional boxing, he is solely responsible for any points decision. In amateur boxing the decision is given by several judges, who sit apart from each other. The difference between a good professional and a good amateur is probably more marked in boxing than in any other sport.

Boxing contests are arranged in classes according to weight, the divisions being: fly-weight, up to 8 stone; bantam-weight, up to 8 stone 6 lb.; feather-weight, up to 9 stone; light-weight, up to 9 stone 9 lb.; welter-weight, up to 10 stone 7 lb.; middle-weight, up to 11 stone 6 lb.; light-heavy or cruiser-weight, up to 12 stone 7 lb.; and heavy-weight, any weight. In amateur boxing some of these weights are slightly different, and there are two additional classes, light-welter-weight, up to 10 stone, and light-middle-weight, up to 11 stone.

Prize-fighting was governed successively by " Broughton's Code," the " New Rules of the Ring," and the " London Rules." Then, in 1867, the eighth Marquess of Queensberry and Mr. J. G. Chambers drew up the rules that have been the basis of boxing ever since. British professional boxing has been controlled since 1929 by the British Boxing Board of Control. The Amateur

Boxing Association has governed amateur boxing since 1884, when it took over from the Amateur Athletic Club, which had looked after both boxing and athletics.

Prize-fighting is finished, but it has left a legacy, not only in modern boxing, but through an expression that has become part of the language, for the phrase "come up to scratch" originally referred to a prize-fighter stepping up for a new round.

Bridge.

Auction. Auction Bridge is a card game in which two partnerships of two oppose each other, each player facing his partner. A complete pack is used, the suits having special values, ranging from 6 points per trick for Clubs, through Diamonds, Hearts, and Spades, to 10 points per trick for No-trumps. When bidding, it is the points value of the bid, and not the number of tricks bid, that decides seniority, though the highest number of tricks prevails when the points values are equal. If a bid, or contract, is doubled or redoubled, the trick score is doubled or redoubled.

A player may pass, but, should he bid under the previous bid, he can be penalised, the player on his left having the option of closing the bidding at the previous bid or demanding that the offender make a proper bid. In this case, his partner is barred from bidding again unless the opponents do so. Should a player bid out of turn, the player on his left can demand a new deal.

Points are counted in two ways, below the line and above it. Points below count towards game (30 points), and are awarded for all tricks over six made by the contracting side. Points above the line are gained in various ways, and count in the final score, but not towards game. The first side to win two games wins the rubber, and 250 extra points above the line. The holding of honours also wins points above the line, as follows: three honours, twice the suit value; four, four times the suit value; five, five times the suit value; four in one hand, eight times the suit value, four in one hand and one in partner's, nine times the suit value; five in one hand, ten times the suit value. At No-trumps the honours count for Aces is 30 points for three, 40 for four, and 100 for four in one hand. The points for defeating a contract are 50 for each trick by which the contract fails. Extra points for making a doubled or redoubled contract are 50 for the contract plus 50 for each trick over when doubled, and 100 for the contract plus 100 for each trick over when redoubled. 50 points are awarded for a little slam, which is 12 tricks, and 100 for a grand slam, all 13 tricks.

The player who first named the contract suit is the declarer, and his partner is dummy. After the lead, which comes from the player on declarer's left, dummy lays his hand face upwards on the table, and it is played by declarer, dummy having only limited rights of intervention. If his partner fails to follow suit, he can ask him if he has no cards in the appropriate suit; he can draw attention if too few or too many cards are played in a trick, or if the wrong side gathers up the trick; he can discuss questions of fact, and correct any claims made by the opponents to which they are not entitled. He cannot draw attention to any revoke; he cannot claim any penalty; and he cannot warn his partner against leading from the wrong hand.

Revoking is failing to follow suit when this is possible, the revoke becoming established when the player or his partner plays to the next trick. Up to then, the offender may correct it. The penalty is 2 tricks for the first revoke, and one for subsequent revokes, the penalty tricks to be taken only from the trick in which the revoke occurred or later ones.

A lead from the wrong hand may not be withdrawn unless the opponents request this. If they do, the card is replaced, and play continues. If declarer's opponents lead from the wrong hand, declarer may either demand a lead in a particular suit from the right hand or reserve the right to have the exposed card played whenever he choos to call for it. In this case, though, the offend may play the card before it is called, if he has opportunity.

Contract. At Contract Bridge only the tric contracted for are scored below the line, ove tricks being recorded above it. The score f tricks is 30 in a major suit (Spades or Hearts) a 20 in a minor suit (Diamonds or Clubs). In N trumps the first trick counts 40 and subseque tricks 30. In bidding, the highest number tricks prevails, regardless of suit values.

A game is 100 points, two games won co stituting a rubber, which carries a bonus 700 points, if the opponents have not won a gam In an unfinished rubber, a game gains 300 poi and a part score 50, provided the opponents have part score at all. A side winning a game becom vulnerable, and this affects subsequent scoring.

Penalties for failing to make a contract a 50 points per undertrick if the declarer is n vulnerable and 100 points per undertrick if he If an opponent has doubled, the penalties are 1 for the first undertrick and 200 for subseque ones if not vulnerable, and 200 for the first unde trick and 300 for subsequent ones if vulnerab If the declarer has redoubled, these penalties a doubled. In successful contracts doubled, ove tricks score 100 if declarer is not vulnerable a 200 if he is. A successful doubled or redoubl contract wins a bonus of 50 points. Bonuses a awarded for making slams, if they have been bi If declarer is not vulnerable, the bonuses are 5 for a small slam (12 tricks) and 1000 for a gra slam (13 tricks). If vulnerable, the bonuses a 750 and 1500. Honours points are 100 for fo honours in the contract suit in one hand; 150 f five honours in one hand; and, in No-trum 150 for four Aces in one hand.

A player making an insufficient bid may required either to pass or to make a sufficie bid. If he passes or makes a sufficient bid in different suit, his partner is barred from furth bidding. A call out of turn is void, but, if it w a pass, the offender must pass in his turn, and, it was not a pass, his partner is barred fro further bidding. A player has no redress if misunderstands a bid, though he can ask for a b or a sequence of bids to be repeated. Wh three successive players have passed, the contra is fixed, declarer being the first player on t contracting side to nominate the suit, and dumm being his partner.

Dummy is entitled to ask for or give inform tion on the laws, to point out revokes and try prevent those about to occur, and to remind h partner from which hand he should lead. however, he looks at any hand other than his ow he forfeits these rights.

If declarer leads from the wrong hand t opponents can demand a lead from the corre hand; and, if it is possible, this must be in t same suit. If a defender leads when it is t declarer's turn, the card becomes a penalty ca If a defender leads when it is his partner's tu declarer may either bar a lead in that suit make the exposed card a penalty card. A pena card must be played at the first legal opportuni

Contract Bridge is a game of systems. The are systems for assessing the value of a hand, a there are more important and more involv systems governing bidding, the object of the being the interchange of information betwe partners.

Bumping Races. *See* Boat Races.

Camping.

Camping expresses the townsman's desire to away from cities and fend for himself in qu But some organisation is necessary to prov camping facilities and to maintain high standar The Camping Club of Great Britain has a memb ship of over 50,000. Its work is twofold:

ects sites suitable for mobile campers and avanners; and establishes and maintains well- ipped permanent camping grounds. A *Sites* t published annually contains details of 2,000 np sites. Members agree to abide by the b's Code of Campers, which stresses the need of camper to pay full regard to the countryman's of life and to maintain by country courtesy goodwill of those among whom he camps. e Club's address is 35 Old Kent Road, London, .1.

adian Football.

anadian Football resembles American (*q.v.*), is twelve-aside, uses only three downs, and its blocking.

oeing.

anoeing is both a recreation and an organised npetitive sport.

s a recreation, it can take the form either of ply taking a canoe out and "paddling about" a short period or, by combining it with Camp- (*q.v.*), of a lengthy and interesting river trip, canoe-camper proceeding, of course, at his pace, and giving as much time as he wishes ightseeing.

s a sport, Canoeing has Olympic Games status. Britain it has its headquarters on the Thames Teddington in Middlesex, the governing body g the British Canoe Union. There are races singles and pairs, including events for women. re is also one long annual race for pairs that ly combines Canoeing with Camping. The rse is from Devizes in Wiltshire to London, the competitors have to negotiate a long es of locks.

here are two types of canoe: Canadian canoes, those used for many years by Red Indians, kayaks, the very light Eskimo-type canoes, hich an expert, but not a beginner, can turn a plete circle into the water and out again with- losing his seat in his craft. Both types are red for in the Olympic Games, but most of the oeing in Britain is in kayaks.

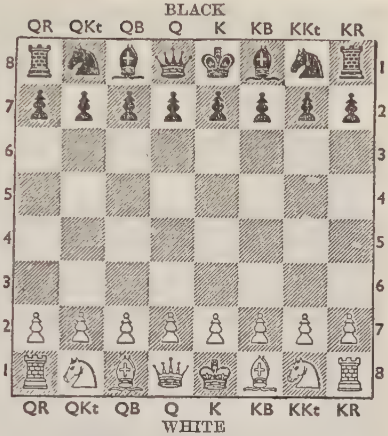
Games. *See* **Bridge; Patience; Solo Whist; st.**

s.

ess, greatest of all board games and a game ure skill, has a known history of some 1500 s. Eastern players, who originated it, ned a high standard, but the game's greatest nces were made in Italy in the fifteenth and enth centuries. In the early days the value e pieces and their moves underwent periodical ges, but the game we know to-day dates from ixteenth century.

e board has 64 squares in eight rows of eight, each player has 16 pieces, one set being white the other black or red, but always referred to lack. A toss decides possession of white, h always starts. The object is the capture e opponent's King, no matter how many s are lost in doing so, nor how many opposing s remain untaken. If the King could be red on the next move, it is in "check." ust be released from check (by moving, by cing, or by capture of the checking piece), rwise it is "checkmate" and the game is over. e King is not in check, but cannot move except check, and the player has no other pieces he nove, it is "stalemate," and a draw. Games also be drawn if neither player has sufficient s to force a win.

addition to the King, each player has a n, two Bishops, two Rooks—sometimes gly called Castles—two Knights, and eight ns, and all these move in accordance with rules. The following diagram shows the s at the start of a game:



(The initial position as seen by White)

Each line of squares across the board is a "rank," and each line up and down the board is a "file."

The permitted moves are as follows:—

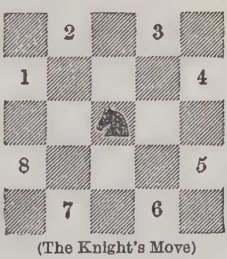
The King ♔ can move one square at a time in any direction.

The Queen ♕ can move in accordance with the powers described below for both Bishops and Rooks.

The Bishops ♗ move diagonally as many squares as desired.

The Rooks ♖ move straight along the ranks or files as far as desired.

The Knights ♘ move as shown in the following diagram:—



(The Knight's Move)

Stationed away from the side of the board, and on a black square, the Knight illustrated can move to any of the numbered white squares. The move is one square along rank or file in the desired direction, and one square diagonally. The Pawns ♙ move straight forward, one square at a time, but may move two squares when moved for the first time. They capture by moving one square diagonally forwards. A Pawn reaching the eighth rank may be replaced by any other piece.

Once during a game, a player may "Castle," by moving the King two squares towards the Rook, which is placed on the last square passed over by the King. This move cannot be made if either the King or any of the squares he would pass over are in check. Neither King nor Rook must have moved previously.

Games of Chess can be recorded, so players can play over great "Masters" games, and record their own games.

Draughts. Draughts—called Checkers in America—is also played on a chess board. Possibly older even than Chess, it is much simpler, but not devoid of skill.

Each player has twelve pieces or "men," all alike. Squares of one colour only are used, the men starting on the first three rows on the board. The move is one square diagonally forward, but a man reaching the eighth row becomes a "King," and may then move forward or backward. The object is the capture of all the opposing men by jumping over them. If the arrangement of the men permits it, more than one man may be captured in a single move. A man which can effect a capture but does not do so is removed from the board, or "huffed."

Cricket.

Cricket, traditionally England's national game, has a longer history than most team games. There have been attempts to trace its origin in various games played by ancient races; and, even if some of these derivations are a little far-fetched, it certainly developed from very old country games, and has been played in a form not so very dissimilar from that of to-day for over 250 years. The men of Hampshire, particularly the village of Hambledon, Surrey and Kent were the real pioneers of the cricket of to-day.

Cricket is played by two teams of eleven players, which bat and field in turn. In the centre of the ground are two "wickets," 22 yards apart, and each consisting of three "stumps," joined at the top by two "bails." The bats used have a flat striking surface, and the ball is a hard red one weighing 5 ounces.

There is a batsman at each wicket, and their object is the scoring of runs by hitting the ball away, and running before it can be returned, each time the two batsmen cover the length of the pitch counting as one run. Should the ball be hit beyond the boundary line round the ground, it counts four or, if it crosses the line without touching the ground, six.

The ball is "bowled" from one wicket to the batsman at the other, six balls, or, in some cases, eight, which comprise an "over," being bowled from each end in turn. The object of the fielding side is to get the batsmen "out," ten dismissals completing the "innings," as the eleventh man is left without a partner.

A batsman can be dismissed in several ways. If he misses the ball and it hits the wicket, or if he plays it on to the wicket, he is out "bowled." If he leaves his ground, indicated by a line in front of the wicket, misses the ball, and has the wicket "broken" by the wicket-keeper he is out "stumped." If he hits the wicket with his bat he is out "hit wicket." If his hit is caught he is out "caught." If, when running, he fails to reach his ground before the wicket is "broken" he is out "run out." If a ball, when bowled, would have hit his wicket, but hits his leg instead, then, subject to certain provisions regarding where the ball actually pitched, he is out "leg-before-wicket." A batsman may also be given out if he handles the ball or obstructs the fielding side, but these are rare occurrences.

In addition to runs hit by the batsmen, there are certain "extras." If the ball passes the bat, misses the wicket, and goes far enough for the batsmen to run, it is a "bye." If, however, it goes off the batsman's leg it is a "leg-bye," but leg-byes cannot be run unless the batsman was definitely attempting a stroke. If it is bowled so wide that the batsman cannot reach it, it is a "wide." If the bowler comes in front of his wicket before releasing the ball, or if he throws it,
it is a "no-ball," in which case the umpire cal
it as quickly as he can, for the batsman can h
such a ball, but he cannot be out to it, unless
is run out. If he does not score, one extra
added.

Of the fielding side, one, of course, is the bowle
and another, placed behind the batsman's wicke
is the wicket-keeper. The others will be place
as the bowler and his captain decide, for there a
far more recognised positions than can be occupie
at one time. To gain some idea of these position
imagine a right-handed batsman at the wicke
his left side towards the bowler. The side of th
wicket in front of him, nearer to his bat than to h
body, is the "off" side; the side behind hi
nearer to his body than to his bat, the "leg" sid
On the off, behind the wicket and close to it, a
the "slips," and, behind them, "third man
Farther round, but still behind the bat a
close to it, is "gully." Level with the bat
"point" or, if he is some way from the bat, "dee
point." In front of the bat, but in front also of th
bowler's wicket, is "cover" and "extra cover
Roughly level with the bowler's wicket is "mi
off," with, behind him, "long off." Similar
on the leg side, where "long on" is the equivale
of "long off," "mid-on" of "mid-off," "mi
wicket" and "deep mid-wicket" of "cover
and "extra cover," "square leg" and "dee
square leg" of "point" and "deep point," "sho
leg" of "gully," "long leg" of "third man," a
"leg slip" of "slip."

First-class cricket matches last for three si
hour days or longer, but there are also two-da
one-day, and half-day matches. Matches of tw
days or more are two-innings games; of one da
or half a day, one innings. If the side battin
first, which is decided by a toss that gives th
winner the choice of batting or fielding firs
dismisses the opposing side for a smaller scor
the victory is by the number of runs by which th
smaller score was exceeded. If the side battin
second pass the other total, the game ends, and th
victory is by the number of wickets the second si
still have standing. In a two-innings matc
should the side batting first gain a first-innin
lead of a certain size, normally 150 runs in a thre
day match, it can require the other side to follo
straight on with its second innings, the leadin
team keeping its second innings in reserve,
be played if needed. If a batting side h
sufficient runs, and is anxious to see the other si
batting while there is still plenty of time
dismiss it, it can declare its innings closed.
this case, should the second team score enou
runs to win, it does, in fact, win, even though
may have lost more wickets than had the decla
ing side.

Cricket is not a fast-moving game, and f
years views have been expressed to the effect th
it must be "brightened up" if it is not to die ou
Periodically, small changes in the rules are mad
but, for the most part, the game just goes steadi
on, easily retaining a large following that
satisfied with it as it is, and still able, when b
international matches take place, to command
place, not only on the sports pages, but on t
front pages of the Press.

The game is unusual in that it has no real
official governing body. It is ruled by the M.C.
which stands simply for Marylebone Cricket Clu
from its headquarters at Lord's ground in Londo
and the M.C.C.'s pronouncements are accept
almost without question.

Outside England, the development of crick
has been peculiar. Even as near at hand
Scotland and Ireland, the game has never arous
much enthusiasm; and in Continental Euro
where many British games have won gre
acclaim, cricket has gained a real foothold only
the Netherlands and Denmark. In the Unit
States and Canada it is played, but only to a sma
extent. However, in Australia, South Afric
New Zealand, the West Indies, India, and Pal
stan, it is extremely popular; and the natio
teams of these countries, together with Englan
provide the top-class international sides of t
game. They meet regularly in "Test Matches
a "rubber" normally being decided in a series
five Tests. *See* **U34.**

Cricket is rich in technical terms and expres-ns, which are seen and heard frequently rough newspapers, television, and radio when a st series is in progress. Many of these are most self-explanatory, but a few never fail to zzle less-experienced readers, viewers, and teners. Prominent amongst these are three pes of ball used by bowlers, the "yorker," the oogly," and the "chinaman."

A yorker is a fast ball that pitches just in the tsman's block-hole, and often passes under his fensive stroke. The term is believed to have ginated in Yorkshire, but the only known planation of it is that attributed to a Yorkshire cketer, who, asked why a yorker was so called, plied simply, "Well, what else would you call " There is an answer to that, for the yorker s originally known as a "tice." A googly is off-break or a leg-break which is disguised, cause the bowler has delivered the one with the ion of the other. A chinaman is an off-break wled by a left-handed bowler to a right-handed tsman. These words also lack an authentic rivation.

Cricket has provided one expression that is now ard in many connections. That is "hat-ck," which dates back to the days when cketers wore top-hats, and any player who k three wickets with three successive balls was sented with a white top-hat. Now, he is ually given the ball.

quet.

Croquet originated in France, and has been yed in Britain for about a century. The gover-g body, the All-England Croquet Club, was nded in 1868, with headquarters at Wimbledon. on afterwards, this also became the head-

nly those portions indicated by a continuous need be marked on the court.

he order of making the points is indicated by arrows.

rters of Lawn Tennis (*q.v.*), and it is probable t the rapid growth of that game was a factor t restricted the development of Croquet. quet, however, still retains a following, and, ddition to Championships and tournaments, s widely played on private lawns.

he equipment consists of four balls, coloured e, black, yellow, and red; four mallets, usually ked with the same colours; six hoops; and g. The playing area is 35 yards by 28 yards, this can be reduced, provided that the propor- remains 5 to 4. The hoops, which stand 1 out of the ground, and the peg are placed as wn in the diagram. Generally two players, ng the blue and black balls, oppose two using yellow and red, but singles can be played, player using two balls, blue being paired with black, and yellow with red. Each player completes the circuit of hoops twice, finishing by hitting the peg.

Croquet is a game of skill, and players can earn extra turns in various ways, such as hitting another ball with their own or passing through hoops. While making their own circuits, players also concentrate on leaving their opponents at a disadvantage. Handicap matches are possible through the giving of extra turns, or "bisques." A "half-bisque" is an extra turn in which no hoop may be scored.

Croquet can, perhaps, claim some credit for a phrase used in everyday life. "Pegging out" has the rather sinister meaning of "dying" or "finishing," but it is actually the term used for finishing a Croquet round by hitting the peg.

Cross-country. *See* Athletics.

Cruising on Inland Waterways.

For those who want a touring holiday in Britain away from crowded roads, but who do not want to walk or ride, cruising on inland waterways offers a pleasant and interesting alternative. Facilities are available on a number of canals, rivers, and, of course, the Norfolk Broads; and motor-cruisers can be hired, complete with sleeping accommodation, bed linen, and cooking utensils. At some places, for example, the upper reaches of the Thames, those who prefer to do so can hire cruisers without sleeping accommodation, and spend the nights at riverside inns. The Inland Waterways Association exists to keep the waterways open and, where possible, to re-open others. Particulars of available facilities can be obtained from the Association at 114 Regent's Park Road, London, N.W.1.

Cycling.

As a pleasant recreation, cycling offers a wide range of possibilities. Outings can be for a day or part of a day, or they can be tours of any length the rider wishes, with the overnight halts spent in hotels or hostels or Camping (*q.v.*), which can easily be combined with cycling.

As a competitive sport, cycling offers a remarkable variety, for no other form of racing provides events of so many different types. On the Continent, cycle racing is by far the most popular sport, and the leading riders are national heroes. The sport, which caters for both amateurs and professionals, also has a large following in Britain, where it would soon progress still farther if there were more tracks suitable for big events available.

Cycle races are held on banked tracks rather like motor-racing tracks, on flat grass tracks, on cinder tracks, on indoor banked board tracks, on roads, and even across country. There are races at all distances, from short sprints to road tours divided into daily stages lasting for several weeks. There are massed-start races, in which all the competitors start together; races in which competitors are drawn in twos or threes through several rounds up to a final; and time trials, in which each rider starts alone. Track races may be straightforward races or time trials; or motor-paced, with the riders behind motor-cycles; or tandem-paced; or pursuit races, with riders or teams of riders starting on opposite sides of or spaced round the track; or point-to-point, with points awarded to the leaders at the end of each lap; or courses des primes, with a prize for the leader at the end of each lap; or Madison races, for teams of two, and occasionally three, riding one at a time, and relieving each other at will. There are also races for tandems and tricycles; and the sport includes races on both track and road for women as well as men.

In the cross-country side of cycle racing, called Cyclo-Cross, riders cover a cross-country course of perhaps 10 miles, riding when they can and carrying their machines where riding is impossible. Still another form of cycle racing is roller racing. In this, the cycles are fixed on rollers, and do not move at all, the distance the riders pedal being registered on large dials. There is also cycle speedway, a sport devised by youths, and practised only by youths. Events take the form of team matches, generally on rough cinder tracks constructed on waste ground by the youths themselves, with pairs of riders opposing rival pairs in a series of races, and points awarded to the leaders in each race. Corners have to be "skidded" round, as they sometimes are in ordinary grass-track cycle racing. Very different, but still competitive in a way, is a form of event that provides a link between the sporting side of cycling and the more purely recreational side, the reliability trial or attempt to achieve a fixed standard.

Cycling also has its team game in Bicycle Polo, a hard game requiring a high level of cycling skill and considerable nerve.

There is also an organisation that caters especially for the distance tourist in the Cyclists Touring Club, which keeps a check on premises offering accommodation to cycle tourists, and provides a sign for use on approved accommodation. It is interesting to note that the Automobile Association, which offers similar services to motorists, but which is not as long-established as the C.T.C., originally based its methods on those of the C.T.C. The C.T.C. address, for those who might be interested in joining, is 3 Craven Hill, London, W.2.

Darts.

Originally just a casual amusement confined almost entirely to public-houses, the game of Darts is now one of Britain's most popular pastimes. Public-houses still provide facilities for it, but to-day clubs, canteens, factories, offices, and private houses also have their boards, and there are numerous team and individual competitions, including a National Championship. The prizes rival those of any other game for value, matches are widely reported, and the attendance for the bigger contests is limited only by the size of the hall. This enthusiasm is not misplaced, for the game is a test of skill, and luck plays little part in it.

The circular board has a diameter of 18 inches, and is divided into segments numbered from 1 to 20, but not consecutively. In addition, there are two rings, each ⅜ inch wide, that go right round the board and through each segment. These are the "double" ring, at the extremity of the board, and the "treble" ring, near the centre of the board, darts in these rings counting double or treble the value of the segment. In the centre of the board there are two small rings, the "bull" or "dosser," counting 50, and the "outer," counting 25. The bull is 5 feet 8 inches from the ground, and the wooden or metal feathered darts are thrown from a line, called the "hockey," 9 feet away.

Matches may be singles, doubles, or between teams of four or eight players. Games are for a certain number of points, usually 101, 201, 301, 501, 801 or 1001, the lower totals being used for individual, and the higher for team contests, and matches are generally the best two out of three games or "legs." Conditions for matches vary, but normally stipulate either "straight start and finish on a double" or "start and finish on a double." In the first case players score from the start, but in the second they do not score until one double has been registered. In both cases they must finish on a double, and they must finish with the exact number they require. Scores are counted downwards, players being told how many they need, rather than how many they have scored.

In addition to the straightforward game, there are many Darts variations. In one, "Round the Clock," a player has to throw one dart into each segment from 1 to either 20 or the bull, his turn continuing until he throws three darts unsuccessfully. In "Shanghai," players start with a complete throw of three darts at number 1, and continue with a throw at every number up to 9, but players who fail to score at number 5 drop out. In "Cricket," one player "bats," throwing normally, and counting everything over 40, while the other "bowls," throwing only at the bull, and counting one wicket for every "outer" and two
for every "bull," five wickets ending his op
ponent's "innings." In a Darts version
Shove-Ha'penny players have to get three dar
in each segment from 1 to 9, and three in th
centre. In "Fives," players score only if the
total is divisible by five.

Diving. *See* Swimming.

Dominoes.

Dominoes are similar in many ways to cards,
that many games can be played with them wit
varying degrees of skill. Players play (or *po*
or *down*) in turn from hands. The game wa
introduced in Europe by way of Italy in the 18t
century, though the actual games as they a
played today, and also the scoring methods, are
French origin.

The domino itself (called a *card* or *stone*)
oblong with its face divided by a centre line a
marked in each half by indented dots. A se
normally consists of 28 pieces, respectively marke
6–6 (double six), 6–5, 6–4, 6–3, 6–2, 6–1, 6–0, 5–
5–4, 5–3, 5–2, 5–1, 5–0, 4–4, 4–3, 4–2, 4–1, 4–
3–3, 3–2, 3–1, 3–0, 2–2, 2–1, 2–0, 1–1, 1–0, 0–
(double blank). (There are special sets for game
consisting of 55 pieces, running up to 9–9, and
pieces, running as high as 12–12).

In the common form of the game, using
pieces, the dominoes are laid face downwards o
the table, each player taking seven, the rest bein
left as a reserve. A player stands his hand
that the faces of his pieces are visible to him bu
not to his opponents. The idea of the game is
match the number on one domino-half to that
the free half of a piece already played on the tabl
Pieces are laid end to end but double pieces a
laid transversely and allow the player an extr
turn. The winner is the one who plays all h
pieces.

Variations include playing a piece that is no
the same as the one to which it is fitted, but tha
with it, adds up to seven, or one that will make th
two ends of the line add up five or a multiple
five, or three or a multiple of three. Anothe
variation makes the double-blank and any piec
on which the two halves add up to seven *mattador*
These are the equivalent of the card player's *tr*
cards, and may be played at any time.

In some games, a player who cannot play simpl
misses the turn, while, in others, he may draw fro
the reserve, having, of course, to retain th
domino in his hand if he still cannot play.

Games are for two, three, four or more player
and, in some of those for four players, two pla
together against the other two, each player tryin
to block his opponents, but to assist his partne

As with cards, solitary players can pla
Patience, and this is a good way for a beginner
learn how to play a hand. The player picks fi
dominoes from a shuffled set, starts with a
piece he chooses, and then continues to play in t
normal way. When he cannot play, he draw
enough pieces from the reserve to make his han
up to five and carries on, continuing until either
can play out or cannot play at all from the piec
left.

In the more skilful games, as in the more skilf
games of cards, a good memory is an asset, as it
essential to remember which player played whi
piece. Despite the claims of many more mode
pastimes, dominoes is gaining in popularit
particularly in such places as works' canteens; a
there are now almost certainly more players
Britain than there have been at any time sin
before the first World War.

Drama

Few countries can boast so eager an interest
amateur drama as Britain, and it is estimat
that there are some 20,000 groups in the Briti
Isles with half a million membership. The car
nal influence in this enormous movement is t
British Drama League, to which some 3,500 grou
belong besides nearly 2,000 private individua

league's influence on drama is exercised in two s. Its members have the use of the library, ch possesses the largest collection of plays and ks on the threatre in Great Britain and of its rmation services, which give help and advice very conceivable dramatic topic. They can, ourse, hire sets of plays (one copy for each racter up to twelve.) Then there are the ue's training schemes. Courses in production, ng, and décor take place in London all the round, and there are summer courses in the ntry. The address of B.D.L. is 9–10 Fitzroy are, London, W.1.

was not until the great International Theatre ibition at the Victoria and Albert Museum in that the English public became fully aware ne "new man" who had arrived in the theatre e "producer" or "director," as the Ameri- call him. It is the producer who decides how play is to be produced and sets his signature n it, very much like the conductor of an estra. In this task he unifies the work of the or, actors, designers, and craftsmen of various s. The technical side of staging a play is a nating one involving problems of the frame- k (the stage, sight lines, auditorium); curtain ngs, lighting, skycloths; the construction of ery; designing the scenery and the making of plans and models; painting the scenery; ing, and so on.

elevision offers new opportunities for the writing aspirant, with its need for new hods. In the theatre the playwright and r must make all things plain to distant mem- of an audience—whereas the television r's slightest change of expression is clear to person sitting within a couple of yards of him. ink, a nod, a shrug on the television screen ce for the implications which would be lost ne theatre. The gearing, so to speak, between and meaning is different. A new field opens, efore, for the writer for television drama.

ghts. *See* **Chess.**

Fives. *See* **Fives.**

ing.

ncing can claim a longer history than most ts, for it is the modern equivalent of duelling. mediæval tournaments mounted knights ht with lances, and, in addition to actual s to the death, they also met with special, lethal lances purely for sport. Later, duels fought dismounted, and with different pons. In Elizabethan days duellists used a d, for attacking, in the right hand, and a er, for defence, in the left. Later still, the er was discarded, and duels were fought, as encing bouts to-day, with a sword only.

uelling declined in Britain during the Regency d, when it became fashionable for gentlemen arn to fight with their fists, but they con- ed to learn swordsmanship, and to fence with practice weapon, the foil. Eventually, ing became illegal almost throughout the l, but swordsmen of other countries similarly nued to fence with the foil. Even before in took to fist-fighting, most of the advances ncing technique had been made in France Italy, and the fencers of these and other inental countries are still the best in the l, countries like Britain and the United es relying largely on fencers of Continental pean descent.

uelling was restricted to "gentlemen," and thing of this restricted atmosphere pervaded arly days of fencing as a sport, clubs being expensive, and rather exclusive. Now, ver, that has changed, and widespread class on in fencing has opened the sport to anyone.

odern fencing includes contests with three ons: the foil, which is the only one used by en; the épée, the real duelling sword; and abre, which cuts as well as thrusts. These ons have "buttons" on the points, but rs wear a special glove, a padded jacket, and sk. Fencing requires grace of movement, lightness of foot, agility, strength of wrist and forearm, quick mental reactions, and good eyesight; and it will do much to develop these qualities, including the eyesight. As masks are worn, it is perfectly practicable to fence wearing glasses.

Figure Skating. *See* **Skating.**

Fives.

There are two games of Fives, Eton Fives and Rugby Fives. They are court games using walls, but an Eton Fives court has the addition of a buttress or "pepper" jutting out from one side wall. The striking implement is the gloved hand. Eton Fives is a doubles game, but both singles and doubles are played in Rugby Fives.

Folk Song and Dance.

Whether or not you play, sing, or dance yourself, you can enjoy the heritage of English folk music, song, and dance. To enable you to enjoy it to the full the story of Cecil Sharp House will be useful. Cecil Sharp went out to collect the folk songs of England in the fields and cottages, in almshouses, and by the roadside. He systematically combed some counties like Somerset. Cecil Sharp and Vaughan Williams joined the English Song Society, which had had Elgar and Parry among its first members. Sharp went on to note down folk dances and to publish details of the steps and figures. In course of time he founded the English Folk Dance Society to restore their traditional dances to the people of England. The two Societies amalgamated in 1932 and, today, Cecil Sharp House (2 Regents Park Road, London, N.W.1) is the home of the English Folk Dance and Song Society, with over 12,000 members.

Scottish Dancing and singing are the primary objectives of special holidays by the Holiday Fellowship at Scottish centres; and Old Time Dancing is enjoyed at an English Centre. Folk dancing is also the feature of special holidays by the Cooperative Holidays Association.

Football. *See* **American Football; Association Football; Australian Rules Football; Canadian Football; Gaelic Football; Public-School Football; Rugby Football.**

Gaelic Football.

Gaelic Football is seldom played by anyone who is not Irish, but it is frequently played outside Ireland, for Irishmen have taken it with them to Britain, the United States, Australia, and South Africa.

Played fifteen-aside, it is a blend of Association and Rugby Football (*q.v.*), the goals having the uprights, cross-bar, and net, exactly as in Association, but having the uprights extended above the cross-bar, as in Rugby. If the ball goes under the cross-bar it is a goal, and if it goes over it is a point, a goal equalling three points. The ball is round, and it may be kicked or caught, but not thrown forward, nor carried, though it may be dribbled by bouncing it. In its essentials, it is probably simpler than most other forms of football, but it is fast and involves frequent hard bodily contact. Substitutes are permitted in case of injury.

Gaelic Football joins with Hurling (*q.v.*) in coming under the old-established Gaelic Athletic Association.

Gliding.

The first serious efforts to develop Gliding which is flying in engineless aircraft or sailplanes making use of natural air currents, took place in Germany in 1919, and were successful enough to lead to experiments in France and England, where it arrived in 1922. At that time, however, it failed to gain much support, and the real history of gliding in Britain dates from a second attempt to encourage it in 1929. Little more than ten years later, gliding had advanced sufficiently to be a real factor in the second World War.

Skilful use of up-currents enables the glider pilot to stay up, and if the air is rising faster than the glider is sinking, the glider will climb.

Gliders can now reach altitudes of over 40,000 feet, stay in the air for over 50 hours, and carry out flights of hundreds of miles. The flying of sailplanes apart from being an exhilarating sport has made important contributions to aeronautical and meteorological research.

Golf.

Golf, a game of great antiquity, originated in Scotland, and is now widely popular in many countries. It consists of using a set of clubs with which to play a small white ball over a cross-country course of eighteen holes. Each hole will be several hundred yards long, and will have its fixed starting-point and its finish with an actual hole in the ground, the object being to complete the course, which will be several miles long, in as few strokes as possible.

The playing of each hole falls into three sections, driving, approaching, and putting. The starting-point will be a flat piece of ground on which the player will "tee up" his ball on a small rubber peg, or "tee," which he will carry round with him. He will then hit the ball towards the hole, concentrating on achieving distance. From the tee to near the hole is the "fairway," which will consist of fairly smooth ground, not entirely devoid of natural obstacles. and probably containing some sand traps, or "bunkers." On each side of the fairway is the "rough," which may consist of long grass, shrubs, woods, or even roads. The player will continue to play his ball towards the hole, concentrating now chiefly on direction. On the fairway or off it, he should always play his ball where it lies, but, should it be quite unplayable, or even lost, he may drop it or a new one, and pay a stroke penalty for the privilege. The actual hole will be on the "green," a rough circle of exceptionally well tended grass, and, once on it, the player will cover the last few yards by the more delicate art of "putting."

There are many different types of club, players being limited to fourteen. The shafts are generally steel, the striking surfaces being iron or, in the case of drivers, wood. The different "irons" have numbers, but golf clubs used to have special names, often descriptive of their functions, for instance, lofter, cleek, mashie, niblick, and even blaster. Originally, most golf courses were by the sea, and these were called "links," a term now loosely applied to any course.

There are two actual methods of competitive play, match play and medal play. Match play is by holes, a player completing any hole in fewer strokes than his opponent winning that hole. Once a player leads by more holes than there are still to play, the game finishes, the victory being by *X* and *Y*, where *X* is the number of holes he is "up," and *Y* the lesser number of unplayed holes. When a player leads by the same number of holes as there are still to play he is said to be "dormy" so many. Opponents level after eighteen holes proceed to the first hole, and play on until one is one hole up, when he is said to have won at the 19th, 20th, or whatever it may be. Some important match-play events are over 36 holes, or two complete rounds. Medal play is simply stroke play, the result depending on the number of strokes needed to complete the course. This demands a higher level of consistency, for one bad spell can ruin the total, whereas, in match play, it may cost only one hole. In play after the initial drive, the player farthest from the hole normally plays before his opponent.

In match-play championships and tournaments players are drawn against each other, the winners going on to the next round, and so on up to the final. In medal-play events players go round in pairs, but each is, of course, playing against the whole field. Team matches consist of singles and foursomes, in which the partners play shots in turn. Other, less-formal forms of golf are four-ball foursomes, in which each player plays his own ball; best-ball foursomes, in which both partners drive, but, thereafter, play in turn only at the most successfully driven ball; and thr
somes, in which each player plays for hims
against the others. During a match, a play
must not receive advice from anyone except
"caddie," if he has one, the caddie being
attendant who makes a profession of carryi
golfers' clubs round.

Every course has its "bogey" and "pa
figures, these being scores, with par representi
the higher standard that a first-class player mig
achieve for the course. By assessing a membe
own scores against these figures, clubs c
allocate a handicap which indicates the playe
standard. There are many minor competitio
in which golfers play, not on level terms, but fr
their handicaps, which also serve as a perpetu
incentive to players to improve their game, a
therefore their handicaps. The possession of
handicap also makes it easier for players
arrange even matches with strangers. Handica
are subject to alteration as a player's standa
changes, and such alterations may be in eit
direction. The operation of the handicap in p
takes the form of strokes deducted from the act
score at certain holes, in accordance with
arrangements in force at any particular club.

Golf offers a tremendous number of competitio
of all standards, as well as championships a
team matches. Probably the four most i
portant individual championships are the Brit
Open, the British Amateur, the American Op
and the American Amateur. These are lo
established, but the two major international te
events are quite new. They are the Canada C
open to teams of two professionals from a
country, and the Eisenhower Cup, for teams
four amateurs, the three best scores counti
from any country. Other, much older int
national team events include the Ryder, Walk
and Curtis Cups, which are contests betwe
Britain and the United States for professiona
amateurs, and women, respectively; though it
interesting to note that the actual inscription
the Curtis Cup indicates that this trophy is op
to women golfers of any country.

Golf is ruled by the Royal and Ancient Club
St. Andrews, Scotland, which is recognised
over the world as the game's headquarters. Th
was an unusual illustration of this widespre
recognition when the Eisenhower Cup competiti
was instituted by the United States in 1958, f
at the special request of the American organise
the first meeting took place, not in the Unit
States, but at St. Andrews. The Royal a
Ancient Club makes the rules of golf, but th
are generally supplemented by local rules in fo
at particular clubs.

The popular expression "rub of the gree
used to describe an unexpected and unavoida
mischance, comes from golf, where it is used wh
a putt fails to take the expected line because o
slight flaw in the normally perfect turf of
green.

Gymnastics.

Gymnastics is a system of exercising with
paratus, and also a competitive sport, the ch
items of apparatus used being the horizontal b
the parallel bars, rings, ropes, ladders, and
vaulting horse. The horizontal bar, the para
bars, and the rings can all be used for simi
exercises, some being fast swings and others sl
movements requiring considerable streng
Strength and swinging also come into lad
exercises; and the rope, which can be climbed
several different ways, is a simple form of
paratus that demands, and will develop, streng
The horse can be used for a variety of vaults,
either the lengthways or sideways position,
still others are possible when pommels are fit
to it. In addition to those who specialise
gymnastics, many sportsmen of various ki
regularly attend gymnastic classes as part of th
training for their own particular activities.

The Trampoline, which is something like a la
and very springy mattress, and which has l
been used by circus and stage acrobats, has
been accepted as a piece of gymnastic appara

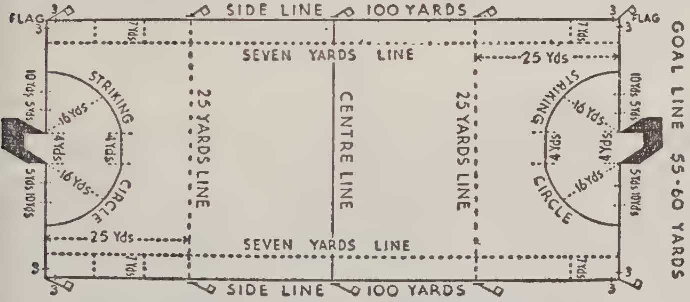
key.

ockey originated about three-quarters of a ury ago as a game confined to Britain, but rules that varied in each of the home tries. However, in 1900, England, Ireland, Wales combined to form the International key Board, with a view to formulating rules would apply wherever the game was played, two years later, Scotland joined the alliance. game was also taken up with terrific enthus- in India, and Indian players became, and ain, the best players in the world. Their usiasm extended to what is now Pakistan, so division that brought that country into ence also added one more to the list of hockey- ing countries, and without noticeably weaken- ndia's own national team.



GROUND.—100 yards by 55 to 60 yards. OPENING OF GOAL.—7 feet by 12 feet.
Diagram of Ground as marked out for Hockey.

ockey is now played in many other countries, for some time, it made little progress on the inent. Eventually, though, it was tried, , and adopted in a number of European tries, and one of these, the Netherlands, has established a right to a place alongside a, Pakistan, and Britain as the game's top . Hockey has, and has long had, Olympic es status.

ockey is played eleven-aside on a pitch marked as in the accompanying diagram, the normal ions of the players being a goalkeeper, two backs, three half-backs, and five forwards, tly as in Association Football (*q.v.*). The ball can be either sewn, as is a cricket ball, eamless, and it must weigh from 5½ to 5¾ es. Sticks must weigh from 12 to 28 ounces, have a handle that can be passed through a with an inside diameter of 2 inches. They a striking surface on the left side only, anded sticks not being permitted. A game sts of two 35-minute halves, unless the ins have agreed on a shorter period.

e game is started, and restarted after half- and after a goal, by a bully at the centre of round. The players bullying stand facing ide-line, each with his own goal on his right. taps the ground between the ball and his goal and his opponent's stick over the ball times alternately, after which one of them play the ball. At any bully, all the other rs must be 5 yards from the ball, and een it and their own goal.

In play, the ball must be propelled only by the stick, and it must not be stopped with any part of the body except the hand, in which case it must only be stopped, and not caught or knocked forward. These prohibitions, however, do not apply to goalkeepers, who may stop the ball with any part of their body, and also kick it, when in their circle. No part of a player's stick must be raised above the shoulder either at the beginning or end of a stroke, or to stop the ball. Hitting the ball in the air and scooping it are allowed, but deliberate undercutting is not, and umpires can penalise any hit which they judge to be dangerous. Interfering with an opponent's stick, running between an opponent and the ball; and charging or other bodily contact are not allowed. Players must not tackle from the left unless they can play the ball without touching the opponent or his stick.

A player is "offside" if there are fewer than three opponents between him and the goal-line, unless he is in his own half, or unless a team-mate playing the ball is nearer to the goal-line than he is. A player who is offside is put onside if an opponent plays the ball, but not if the ball merely touches or glances off the opponent. Players who are offside are not penalised if they do not interfere with the play.

If the ball crosses the side-line it is rolled in by a player of the side that did not put it out. This player must have his hands, feet, and stick outside the field of play, and he must not play the ball again until someone else has done so. All the other players must have their feet and sticks inside the 7-yard line until the ball leaves the roller's hand.

If the ball is sent across the goal-line wide of the goal by an attacker, or, unintentionally, by a defender who is more than 25 yards from the goal-line, the restart is by a bully on the 25-yard line. If it is hit behind unintentionally by a defender who is within 25 yards of the goal-line, a corner is awarded to the attacking side. If it is hit behind intentionally by a defender from any part of the ground, a short, or penalty, corner is awarded to the attacking side. A corner is a hit from a point on either the goal-line or the side-line within 3 yards of the corner flag, while a short corner is a hit from a point on the goal-line 10 yards from the nearer goal-post. At a corner, all the defenders must be behind the goal-line, and all the attackers outside the circle. When the corner hit comes into the circle, attackers are not allowed to take a first-time shot, but must first stop the ball or slow it down. At no time during the game can a goal be scored unless it was hit from inside the circle.

Penalties for infringements outside the circles are generally free hits. Penalties for infringements inside the circle by defenders are short corners, unless they have been deliberately committed to prevent a goal, or have, in fact, prevented a goal, in which cases a penalty bully is awarded. In extreme cases, both short corners and penalty bullies can be awarded for offences anywhere behind the 25-yard line.

In 1963 the penalty stroke was introduced. This replaced the penalty bully, a duel between the offender and one opponent, with all the other players beyond the 25-yard line, that started with a bully 5 yards from the centre of the goal and continued until either a goal was scored or the ball was hit behind the attacker or out of the circle by the defender. If it was hit behind by the defender, the bully was restarted. This was a novel feature, but a not altogether satisfactory one, as the duel was sometimes protracted. The penalty stroke, if less spectacular, is also less complicated.

A game is controlled by two umpires, each of whom takes one half of the field and one complete side-line. Substitutes are not permitted in hockey.

Hockey is entirely an amateur game. Almost every match is a friendly, for, in Britain, there are no leagues and only a very few rather specialised cup competitions. There are, however, a great many representative games, from county matches up to internationals.

A major feature of the hockey season, which normally lasts from October until March, is the end-of-season Easter Hockey Festival. There are actually several festivals, most of them taking place at seaside resorts. Teams go to them from many different areas, including the Continent, and play three or four matches in four days against opponents whom they would not normally meet. Six-aside tournaments also take place occasionally during the season.

Hurling.

Hurling, which might loosely be called the Irish brand of Hockey (*q.v.*), is played fifteen-aside, and has been described as the fastest game using a ball in the world. The ball, called the "slitter," and the sticks, called "hurleys," bear some resemblance to Hockey's ball and sticks, but nothing like Hockey's "sticks" rule applies. The slitter may be hit at any height, and with either side of the hurley, and it may be kicked or caught, though it must not be carried more than three steps, nor picked up off the ground. There is no offside, apart from the fact that attackers must not enter the parallelogram marked out near the goal ahead of the slitter. The goals have uprights that are extended above the cross-bar, and scoring is by goals, under the bar, and points, over the bar, a goal equalling three points. There is a good deal of bodily contact, and substitutes are permitted for injured players.

Hurling, rarely played by anyone who is not Irish, but often played by Irishmen outside Ireland, is of great antiquity, and the English authorities in Ireland first tried to suppress it six hundred years ago. It was kept alive, however, and it is very much alive to-day. To Irishmen, Hurling and Gaelic Football (*q.v.*) are symbols of nationalism and patriotism. They are governed by the Gaelic Athletic Association, which has a rule that states: "Any member who plays or encourages Rugby, Association Football, Hockey or Cricket by that very fact incurs immediate suspension from membership of the Association."

A form of Hurling with slightly different rules, called Shinty, is still preserved in another Celtic country, Scotland.

Korfball

Korfball is a team game with several unique features, the most striking being that it is a mixed game, a team consisting of twelve players— men and six women. The game resemb Basketball (*q.v.*) in some ways, the goals, whi are 11½ feet high, and the scoring of goals bei similar. It can be played on any firm surfa the pitch measuring 300 feet by 133 feet, thou a smaller pitch can be used, provided that leng and width are reduced in proportion. The pit is divided into three sections, and players do move from one sector to another during actu play. They must, however, change to anoth zone after every two goals. This encourages round attacking and defensive ability, and ensu that, even in a one-sided match, every play gets a fair share of the game. Four players fro each team play in each section, and players alwa mark opponents of their own sex. Players must run with the ball which is advanced purely passing. There is no tackling, and the ball only pass from one team to the other by int ception. Players may not score if there is opponent within arm's length. A game lasts 90 minutes, divided into two halves.

Korfball originated in the Netherlands, where was first played in 1902. It spread to Belgium 1927, and reached England in 1947. There is International Board, on which the Netherlan Belgium, and England are represented. Int national inter-club matches are a regular featu of the game. Though really a winter gam Korfball is actually played all the year rou the international games between clubs from t three Korfball countries taking place during t summer.

Lacrosse.

Lacrosse, which originated from a game play by the Red Indians, was introduced into Engla from Canada in 1867, and has been played he ever since.

Basically, it is, perhaps, the simplest of field team games. The object is the propelli of a rubber ball through goals 6 feet wide and feet high with a wooden "crosse" not more th a foot wide at its widest point, where there is "mesh" of strings. The goals are from 90 110 yards apart, but play can take place behi them, for there are no boundaries to the pit except the natural borders of the field, unless t captains have agreed otherwise. The only lin required are the centre circle, the goal-lines, a the goal-creases.

In England teams consist of twelve playe but in Canada and the United States the numb was reduced to ten some years ago. Playe line up right down the field, instead of only their own half, and there is no offside, except th no attacker may enter the goal-crease before t ball. Should a player leave the field throu injury, his opponents must also withdraw a ma

A game consists of four 20-minute periods, b the captains can agree to vary this, either to t 45-minute halves or otherwise. The game started or re-started after a stoppage by o player from each side "facing" by placing t ball on the ground between the backs of the t crosses, and then drawing them apart, aft which the ball is in play. It can then be advanc by running with it on the crosse, throwing it fro the crosse, or kicking it, though no goal, except "own goal," can be scored by a kick. Only t goalkeeper, who can deflect the ball with his han but not catch or throw it, may handle the ba Players can shoulder opponents when trying get the ball off the ground, and "body check them by simply standing in front of them impede them. A player can also check opponent's crosse with his own crosse if t opponent has the ball. A foul is penalised giving the non-offending player a "free positio which means that he is given the ball, and t game is then re-started.

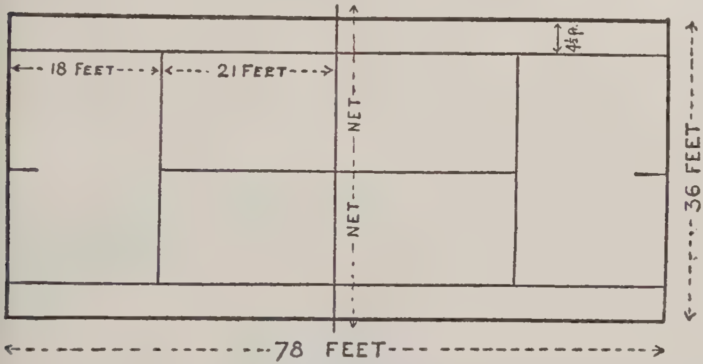
Lacrosse demands speed and stamina, and high level of skill demands practice, but it is hard for a beginner to grasp the main objects master the comparatively simple rules.

It is interesting to note that Lacrosse, whi can be one of the roughest of all games, has be le a suitable game for women by very simple asures, such as the elimination of the body ck; and that there are now more women ving than there are men.

vn Tennis.

riginally called Sphairistike—or "Sticky" by se who disliked it—Lawn Tennis was invented he seventies of the last century as a simplified, loor version of Real Tennis (q.v.), using a net, no walls. It is now far more widely played n the parent game, being popular almost all r the world. As its name implies, it was inally intended to be played on grass, but it ow also played on hard courts of various aces, and indoors on wood.

he court is as shown in the accompanying ram, the outer long boundary lines being the tations for doubles, and those parallel to n being the boundaries for singles. Both er and receiver score, four points making a e, six games won a set, and two out of three ree out of five sets won a match. Game s are scored "15," "30," "40," and me." The system of "vantage" games sets is used. This means that, if 40-all—l "deuce"—is reached, a player must gain ar lead of two points to win the game, the er of the first point after deuce being said to the "advantage." If the games reach 5-all, et continues until one player has a clear lead o games.



NET:—Height 3 ft. 6 in. at posts, 3 ft. at centre.
Diagram of Ground as marked out for Lawn Tennis.

nen the game began, there was considerable ssion before this scoring, which is taken from is, was given preference over the straight-ard one-two-three system of Rackets (*q.v.*). more recently, experiments have been made the equally straightforward system of Table is (*q.v.*), but the Tennis system survived , and remains in force.

vice is almost invariably overhand, and the ver plays the service after one bounce. eafter, strokes may be "ground" strokes, d after one bounce, or volleys, played before ounce. In doubles, either partner may play all, but each must serve in turn.

addition to being played by thousands of e, Lawn Tennis attracts large crowds of ators. The big annual tournaments, such Vimbledon, Forest Hills, and Paris, are gst the major sporting events of the year; the Davis Cup competition, open to teams n from every country in the world, and the tman Cup, a women's contest between Britain he United States. All these events are ama- but the game also has a top layer of profes-s, whose annual world tours are a great at-on.

es. *See* Old English Games and Customs.

Modern Pentathlon.

Imagine a king's messenger riding with an important dispatch, and being hotly pursued. His horse is shot, and he has to engage his pursuers, first with his revolver, and then with the sword. Eventually, he breaks away, swims a river, and finishes his journey on foot and running.

That is the "plot" on which is based one of the most interesting, exciting, and testing of all sporting events, the Modern Pentathlon. Often wrongly thought to be a part of Athletics, the Pentathlon is a separate sport, but one that actually consists of five different sports: the five activities, in fact, of the king's messenger in the story, riding, revolver shooting, fencing, swimming, and running. True, the Pentathlon competitor does not have to carry them out one after the other, but he does have to take part in them in that order, one on each of five successive days, both riding and running being across country, the riding on a horse strange to him.

The Pentathlon first appeared in the Olympic Games of 1912, but, in recent years, it has become so popular that, in addition to the Olympic event every four years, there are now annual world championships, as well as national championships in many countries, including Britain. The event was originally designed as one suitable for Army officers, and, though present-day Army training is rather different, most Pentathlon competitors are still servicemen, though they are not all officers. However, a civilian has won the Olympic event, and, in Britain, the Army authorities are willing to provide training facilities for civilian competitors who show signs of reaching a high standard. Many people believe that the "keys" to success in the Modern Pentathlon are swimming and running, and that competitors who are good at them can be taught the riding, shooting, and fencing without too much difficulty.

Mountaineering.

Among famous peaks, Mont Blanc was first conquered in 1786, the Jungfrau in 1811, and the Wetterhorn in 1854. By then, Mountaineering was becoming organised, and there were systematic assaults on the Alps; in Norway, the Caucasus, and Corsica; in the Rockies and the Andes; in Japan, New Zealand, and Kenya; and, of course, in the Himalayas, where over thirty years passed between the first assault on Everest and its conquest in 1953. There are still unconquered peaks in the Himalayas, but it is not only first ascents that interest the mountaineer; he can find exciting climbing in many parts of the world.

The way to master Mountaineering is to accompany and watch experts. Perfect physical and nervous fitness is essential, as is a detailed knowledge of snow, ice, avalanches, glaciers, crevasses, and cornices, and of the different techniques of ascending, descending, and traversing. Also to be learned is step-cutting, which is hard manual labour carried out under difficult conditions, conditions that may make perfect workmanship literally a matter of life or death. Clothing, properly nailed boots, ropes, ice axes, knives, maps, compasses, medical supplies, must be of the best, and yet, at the same time, light.

Mountaineering is generally taken to mean snow and ice climbing, but allied to it is Rock-climbing, which demands the same perfect physical and nervous condition, and, in place of knowledge of snow and ice, knowledge of several very different kinds of rock. Ascending, descending, and traversing all apply, and so do ropes, and the rock-climber should, in fact, be something of a knot expert. Light, rope-soled shoes replace the mountaineer's nailed boots. Skye is a favourite haunt of rock-climbers, and, in view of what might justifiably be called the antiquity of climbing, it is surprising to note that the highest peak in Skye, Sgurr Alasdair, was not conquered until 1873.

The Mountaineering Association, 102A Westbourne Grove, London, W.2, runs training schools for climbers at all stages in Britain and abroad; and also runs evening classes on rock climbing in conjunction with education authorities. The Holiday Fellowship organises climbing tours in the Highlands of Scotland, climbing many well-known mountains. In Scotland useful addresses are the Scottish Mountaineering Club, 406 Sauchiehall Street, Glasgow, C.2, and the Junior Mountaineering Club, 28 Croftmont Avenue, Croftfoot, Glasgow, S.4. At the White Hall Centre for Open Country Pursuits, Manchester Road, near Buxton, the Derbyshire County Council hold courses for those between 13 and 20 plus on hillcraft, rock climbing, camping, ski-ing, and canoeing. The Outward Bound Trust, 123 Victoria Street, London, S.W.1, runs schools in Wales and the Lake District to train boys—with a few courses for girls—how to face hazards and hardships of all kinds on mountains and sea.

Music.

One of the most novel changes of the last generation or so has been the widespread diffusion of music not only in this country but all over the world. Twenty or thirty years ago it might have been necessary to travel a long way to hear the performance of a classical musical work; and the opportunity of doing so was only occasional. We can now have a constant flow of such music from wireless and record player. Several things follow from this change. Leisure has been transformed by " high fidelity " and the long-playing record. People listen more easily and frequently than they read; and it is music, rather than literature, which is at the centre of culture. Access to good music does not depend upon training and application to the same extent as access to good literature. It is easier for the tired person to enjoy music than a serious book. " Where the library shelves used to stand," says a commentator, " there are now the record albums, row upon proud and esoteric row." The listener may well be submerged, by the easy flow of music of vastly different kinds; but there is an opportunity for the discerning listener to compare and to select from the music of the different centuries, to study the difference between the classical and romantic masters, the emergence of modern orchestration, choral music, chamber music, opera, and oratorio. We may go on to study other aspects—the study of the personality of the composers; the relation between their work and the problems of the times; knowledge of the different instruments; and how to enjoy reading a musical score. By this means the listener can combine refreshment of spirit with the delights of exercising skills of various kinds.

All through the summer, all over the country there are opportunities for music lovers, whether active musicians or not, to spend a holiday together and pursue some aspect of music. The reader will probably be surprised to learn that there are nearly one hundred such summer schools each year, some for the week-end, others for a week or fortnight. The Rural Music Schools Association at Hitchen, Herts. would help e quirers for particulars. A glance at the annu list shows how wide are the subjects offere madrigal and other singing, recorder playin orchestra and chamber music, Russian musi 18th-century music, discussion for wind teache the making of musical instruments. These sur mer schools are in addition to the Music Festiva held at Edinburgh, Bath, Cheltenham, and oth places, not forgetting the Three Choirs Festiv in the West (British Federation of Music Festiva 106 Gloucester Place, London, W.1). Details the various continental festivals can be obtain from the European Association of Music Festiva 122 rue de Lausanne, Geneva, or 82 Beauchan Place, London, S.W.3.

Your local public library probably has a mus library. The National Operatic and Dramat Association, 1 Crestfield Street, London, W.C. has a library of musical scores and dramatic work The National Federation of Music Societies pul lishes a catalogue with practical details of son 500 choral works and assists music societies l advice, information, and in other ways; i address is 4 St. James's Square, London, W.C. The Workers Music Association provides oppo tunities for developing musical instincts and taste believing that genuine art moves people to wo for the betterment of society. It organises classe lectures, and week-end and summer schools; ar offers correspondence courses in Harmon Counterpoint, and Orchestration. Its address 17 Bishops Bridge Road, London, W.2.

Many local authorities have record departmen in their local libraries. The Central Gramopho Library (38 Russell Square, London W.C.1) has circulating library of records which are availab to adult education lecturers, music and gram phone societies and to hospitals and prison Those interested in forming a gramophone socie should get into touch with the National Federati of Gramophone Societies. The British Institu of Recorded Sound, 38 Russell Square Lond W.C.1 contains the national archives of gram phone records and other sound-recordings and the national centre for information and doc ments.

Natural History and Field Studies.

There are seven Field Centres in England a Wales, at:

Juniper Hall, Dorking, Surrey.
Flatford Mill, East Bergholt, near Colcheste Essex.
Malham Tarn, near Settle, Yorkshire.
Dale Fort, Haverfordwest, Pembrokeshi (including Skokholm Bird Sanctuary).
Preston Montford, near Shrewsbury, Shro-shire.
Slapton Ley, Slapton, Kingsbridge, Devo shire.
Orielton, near Pembroke, S. Wales.

Two new field centres are planned to come in operation during 1967, at Nettlecombe Cou Williton, Taunton, Somerset, and Rhyd-y-Creu Betws-y-Coed, Caernarvonshire. The seven ce tres have been set up by the Field Studies Coun in localities selected for their ecological featu and for their geological, geographical, archaeol gical, and artistic interest. Working faciliti and expert guidance are available at the Fie Centres to all who have a serious interest in t countryside—whether as amateur naturalists as students or as research workers. They are n reserved for the academic student only. T Council want to encourage and help the beginn and the ordinary person who has an interest some branch of natural history and wishes learn of this or allied subjects. The Centres a staffed and suitably equipped to provide re dential accommodation and working facilities f numbers ranging up to about sixty persons. Th field workers enjoy the skilled guidance of t staff, local contacts and information, ben space, tools, maps and records, with something the intellectual and social life of a small resident college. There are special courses for amateu and some of these are less formal than the wo " course " suggests. The subjects vary wide luding bird study, land structure and scenery, l outdoor painting and sketching.

uniper Hall, amidst the beautiful chalk hills of North Downs, is well situated for almost every d of field study. Flatford Mill is at the head of Stour estuary, in the countryside of Constable l Gainsborough. The Stour, with its tributary eams, its mill pools and cattle ponds and dykes, vides excellent scope for water biology. lham Tarn Centre is on the shore of the tarn on limestone uplands at the head of Airedale in Yorkshire Pennines. Here is the rich flora of l-drained pastures, screes, and limestone. The n itself supports an abundant fauna of in- tebrates and fish. Dale Fort at the tip of a row peninsula guards the approach to Milford ven. The flowers on the cliffs in May and June the envy of the rock gardener. The oppor- ities for the marine biologist are unsurpassed. t there is no specialisation to the exclusion of of the many subjects that can advantageously studied. The Bird Observatory on Skokholm nd is a part of Dale Fort Field Centre, and here k on birds has pride of place. Guillemots and orbills breed on the rocks, and puffins and arwaters burrow in the edges of the plateau. ston Montford lies on the banks of the Severn r miles west of Shrewsbury, where geological mations are displayed conveniently for study. the North Shropshire plain is scope for the dy, too long neglected, of the ecology of inary English farming country that man has uenced for more than 2,000 years. There are nerous localities of archaeological interest, luding the Roman town of Viroconium. At pton Ley the 300 acres of Slapton Nature serve offer ample scope for interest in most nches of Natural History. The Ley is separa- from the sea by a shingle bank. There are orland and bog: slate and limestone cliffs; e shores and beaches; and woodlands. En- ries can be made to the Field Studies Council, vensmead, Keston, Kent.

Everyone who *wants* to work in the field can find nething useful to do, whatever his natural bent l his training, since the range of research is t and the problems diverse, with such varying rees of difficulty. This opportunity has been atly extended by the increasing importance of logy, which is a distinctive point of view in the oroach to field biology. In its most general se ecology may be defined as the study of plants l animals as they live *in their natural homes*. e growing popularity of the subject in this ntry represents a breakaway from the confinement of serious work in biology to the laboratory l museum. These are still, of course, absolutely essary, but the primary place in which to work ecology is the field.

3ird-watching. The pleasure of bird-song and sight of their activities is a common one for st of us. From this point many are prompted make a closer study of birds and their habits. get the most pleasure it is a great advantage to n for advice to those who have had a wide experience. The enthusiast will thus become ipped with some knowledge of methods of bird- tching, how to make field notes and keep ords, hides, identification, tables of family like- s, migration, sanctuaries, bird photography, l the structure of the bird.

3ird-watching is not confined to those who live he country. London has probably more bird- tchers than any other part of Britain. With possible exception of the parish of Selborne in mpshire, immortalised by Gilbert White, ndon, has the longest continuous history of ithological observation in the British Isles. ups of enthusiastic naturalists have collected ass of detail about wild birds and their habits in ndon. The list of London birds is not only raordinarily large but also contains many ities and many birds of great scientific interest, the black redstart and the little ringed plover. ere are also special London problems, like the sting of starlings in central London and the in of this starling population. The reservoirs l the river, the commons and woods and park- d around London offer pleasant places for ervation. The London Natural History Society (headquarters, the Natural History Museum, Cromwell Road, S.W.7) has, as its chief object, the study and enjoyment of natural history in the London area.

Visiting Nature Reserves. The Nature Conservancy welcome visitors to National Nature Reserves within the limits set by the Conservancy's own responsibilities towards these lands and their plants and wild life. The Reserves are maintained on behalf of the nation to conserve their natural fauna and flora, and so far as possible to enhance their interest and value to science. As far as possible the Rseerves are accessible for the use and enjoyment of all who are prepared to respect the necessity for handing them on unimpaired to future generations and for avoiding interference with scientific work. Many Reserves are accessible without formality; elsewhere a permit is required. A list of the Reserves is obtainable from the Conservancy, 19 Belgrave Square, London, S.W.1, or in Scotland from 12 Hope Terrace, Edinburgh, 9. There are some eighty National Nature Reserves. Among the extremely small reserves is, for example, the North Fen Reserve, 4 miles S.S.W. of Ambleside showing a vegetational succession of open water rich in mineral salts to fen, carr, and bog. The largest in Britain is the Cairngorms in Scotland, of nearly 40,000 acres, with fauna rich in variety of species from wild cats to golden eagle and a diverse flora, which includes the arctic-alpine plants of the corries, screes, and exposed summits.

The Council of Nature. If you are interested in any aspect of natural history—for example in plants, birds, rocks, insects, trees, butterflies, or natural history photography—you will have no difficulty in finding the address of your local history society, of which there are a very large number. The local public library would doubtless give you the address you want, or you could enquire from the Council of Nature, 41 Queen's Gate, London, S.W.7. to which over two hundred organisations belong. These include the Royal Society for the Protection of Birds, which has upwards of 9,000 members and runs the Junior Bird Recorders' Club for young people interested in bird-watching. The Council links amateur and specialist in the study of natural history and the conservation of wild life. It has an Intelligence Unit which is ready to deal with requests for information on field natural history in the United Kingdom. The Film Officer of the Unit will advise amateur still and ciné photographers on all aspects of natural history photography. He will also be able to advise on what natural history films are available and on likely sources for photographs of any British wild animal or plant.

Netball.

Netball, which is played exclusively by women, is similar to Basketball (*q.v.*), but it is played seven-aside, does not allow substitutes, and the goals have no backboards. It is almost always played outdoors on asphalt or grass.

Nine Men's Morris. *See* Old English Games and Customs.

Old English Games and Customs.

The story of England had its beginnings a very long time ago, and many of England's present-day customs, recreations, sports, and games can be traced far back in that story. Some, of course, have undergone very considerable changes, but the links with the past are still clear.

On 1 May, for instance, girls still awake in some villages to the realisation that they are to be May Queens, and to reign for a day, though they may not realise that they are preserving a custom that can point to origins in the days of the Druids, and that, in Tudor times, would have sent them and their fellow villagers out to spend the preceding night in the woods, gathering branches of trees and flowers with which to decorate their houses. Maypoles and morris dancers also belonged to May Day, and they can still be seen in England, and not only on that day.

More local, even quainter, but equally traditional is the trial for the Dunmow Flitch of Bacon in the village of Dunmow in Essex. The original conditions offer this award to any married couple who will go to the twelfth-century Augustinian priory, and there kneel on two sharp-pointed stones and swear that they have neither quarrelled nor repented of their marriage within a year and a day of its celebration. This award has lasted into modern times, not annually, it is true; but then it never was given annually, for it was instituted in 1244, and first claimed in 1445.

One annual event that is as traditional as it is strenuous in the Whit Monday cheese-chase at the village of Brockworth, near Gloucester. Records of this go back to the days of the Stuarts, for that was when they started to keep records of a custom that was already old then: so old that its origins are unknown, though they had to do with the villagers' cattle-grazing rights. A massive round cheese is rolled down nearby Coopers Hill, which has a gradient of one in four throughout its 150 yards; and, with a certain amount of risk to life and limb, the chasers tear down after it, the cheese being the prize for whoever catches it. Sometimes, the cheese hits a bump, and literally leaps out of reach over the hedge at the bottom of the hill, but the chase continues, the prize going to the first pursuer to reach the hedge, where "catchers" wait to halt the headlong rush of the runners. Despite the obvious dangers, the records to date mention nothing worse than a sprained ankle.

This brings us to sports and games; and, though today's most popular game, Football, is, in anything like its present form a comparatively recent growth, it can perhaps claim some relationship with Harpastum and Campball, which existed before the Norman Conquest; and it was one of the popular recreations banned in the interests of Archery. The football of those and later days, however, took the form of struggles between whole villages, the players battling *en masse* over a cross-country course of several miles. People past whose houses the battle was likely to rage prudently barred and shuttered all windows and doors, awaited the cessation of hostilities with anxiety, and probably helped to push this particular custom into oblivion.

The oldest English games are old indeed, and Cricket, too, had remote ancestors, from which the descent to today can be traced more directly. They included Bat and Trap, Creag, Cat and Dog, and Rounders. In Bat and Trap, the batsman hit a ball released from a trap between two posts. His opponent rolled it back underarm at the trap flap. If he knocked it down, the batsman was out; if not, the batsman scored one run and had another hit. This game is still played in Kent. Creag, which was played at the time of Edward II, used a curved stick, called a "cryc," as a bat, and a tree-stump as a wicket. Cat and Dog, which came later, was a game for three, two batsmen defending holes 13 yards apart, and trying to hit away the piece of wood that the third player aimed at the holes, the bats being the "dogs" and the piece of wood the "cat." It is worth noting that Baseball's accepted ancestors are games called One Old Cat and Two Old Cat, which clearly indicates a common origin for Cricket and Baseball. Some of the games in Cricket's ancestry remained popular after Cricket arrived, and Rounders is still a popular children's game.

The beginning of Athletics can also be found in old England. Putting the weight and casting the bar, a forerunner of throwing the hammer, were popular with the courtiers in Tudor days, while other events, including javelin throwing, were practised by ordinary people of the same period. Later, the early hammer throwing spread beyond the Court, and was even attempted by women, which modern hammer throwing is not.

Tournaments and jousts were popular from the Middle Ages until Tudor times. These were combats between mounted men, a joust being single combat, while a tournament involved many contestants. They were succeeded by dismounted combats, which still take place today in the sport of Fencing. Those taking part in tournaments and jousts were required t swear an oath to the effect that they were com peting purely for sport; and those taking part i the Olympic Games and certain other big sport meetings to-day swear an almost identical oath Somewhat similar to jousting, but not restricted as jousting was, to the nobility, was Tilting at th Quintain, which was practised both mounted an on foot, and in which a lance was thrust at wooden target, which, if not struck accurately swung round and struck the tilter.

Other old games, clearly the ancestors c modern ones, included Handball, which becam Fives, but which is still handball in the Unite States; Battledore and Shuttlecock, still children's game, but now developed by adult into Badminton; and Shovelboard, an elaborat game, for the nobility, which consisted of slidin weights down a long table marked with lines, an which is certainly a forerunner of Shove-Ha'penny. Another probable ancestor of Shove Ha'penny was Squails, in which a coin was place in the centre of a round table, and players trie to push their "squails," or discs, as close to th coin as possible, distances being measured by a instrument called a "swoggle." Also known a Skayles and Keels, this game appeared in th sixteenth century, lasted into the nineteent century, and, under the name of Keels, achieve a poetic mention in Sidney's "Arcadia."

Archery. Archery goes back hundreds of year to the days when the bow was the chief weapo of war, and, because of that, practice shootin and contests were officially encouraged: encouraged, in fact, to the extent that other popula recreations, like Football, Quoits, and Bowl that might have interfered with it were banne though the bans were always largely ignore Eventually, the bow disappeared from the battle fields, but, to this day, it has remained popula as a means of recreation and sport. Throug the centuries, archery contests were generally c three kinds: shooting at a mark, or target shooting purely for distance, though this wa more popular abroad, in countries like Turkey than in Britain; and shooting at "rovers," i which two or three archers would cover a cros country course, taking it in turns to select a mar at which to shoot. To-day, archery, which retai enough of tradition in its terminology to remin the archer that he is following in a very long lin consists of shooting at a target containing rin coloured, going from the centre outwards, gol red, blue, black, and white, the values bein respectively, nine, seven, five, three, and one.

Knur and Spell. Knur and Spell belongs t Lancashire and Yorkshire, and originated in children's game called Trap and Ball. The playe uses a wooden club, the striking end of whic called the "pommel," is shaped something lik a bottle, though it has a flat hitting surface, wit which to hit a small ball, which he himself release from a trap by means of a trigger. The bal which is the "knur," weighs ¼ ounce, measures inch in diameter, and was originally wooden though, later, porcelain was used. The trap the "spell," and consists of a small brass cup wit a strong spring, which is kept down by the trigge The fixing of the spell is an elaborate proce requiring the use of a spirit level, and, when it in position, a player is allowed 10 minutes adjust the tension of the spring. Players gene ally have their own spells. Each player has fiv consecutive hits, or "rises," and scores one poi for every 20 yards covered.

Marbles. Marbles is supposed to have bee played in ancient Egypt, but its popularity, wit adults as well as children, in the England of th Middle Ages entitles it to count as an old Englis game. Marbles are often made of clay, but bett ones are glass, and the best are pure marbl These are called "alleys," or "alley taws." The are several games of marbles, but they all invol the aiming of a marble at a target, which may another marble or an opening, by bowling "shooting" it along the ground. In shootin

marble is held between the thumb and fore-
er, with the knuckle of the forefinger on the
und, and is then flicked away.

erhaps the best-known game is Ring Taw, in
ch players shoot from one circle at marbles
ed in another about 6 feet away. Fortifica-
s and Increase Pound use concentric circles,
vers shooting at marbles in each circle in turn.
ee Holes and Handers involve shooting at holes
he ground; Arch Board or Bridge, at arches
n upright board; and Die Shot, at another
rble on which a numbered die is balanced.

ine Men's Morris. Nine Men's Morris is a
teenth-century game for two, usually played
doors on a diagram marked on the ground,
sometimes played indoors on a board. The
gram consists of three squares drawn inside
h other. In addition to the outlines of each
are, there are lines from the centre of each
of the inmost square, through the centre of
sides of the middle square, to the centre of
sides of the outermost square. The corner
ach square and the centre of each side are the
points of importance in the game. Each
ver has nine men, often counters, and they
in turn, placing a man at an unoccupied
t, and endeavouring to place three men in
row, continuing, when all the men are placed,
ry to form rows by moving men along the
s. The completion of a row entitles a player
emove, or "pound," one of his opponent's
, the object of the game being either the
ure of all the opposing men or blocking them
hat they cannot move. The game has many
ations, and many names, including ninepenny
ris; fivepenny morris, for a version played
h five men; and merils, marls, marrels, morals,
ris and miracles, all for a version played with
e men.

all-Mall. Two London thoroughfares, Pall
and the Mall, are reminders that Pall-Mall
once popular. Often described as a fore-
ner of Croquet, it was really more like a form
olf, a game that arrived at about the same
, both having a common, if remote, ancestor
he Roman game, Paganica. In Paganica
ers walked across fields hitting a small,
ner ball at trees with a curved stick, the object
g to reach the target in the fewest possible
kes. It was played by country people,
reas pall-mall, which achieved rapid popu-
y in the seventeenth century, was a game for
nobility, though other people played simplified
ions of it. Pall-Mall was played in special
s, sometimes ½ mile long, and often sur-
ded by walls. A boxwood ball a foot in
umference had to be played down the alley,
hich were a number of iron arches, in the
st possible strokes. The player drove off as
olf, but, on reaching the arches, not only
ged his club, but also substituted a small
ball for the boxwood one.

uoits. Dating back to the fifteenth century,
its is one of those ancient games that had the
nction of being banned because its popularity
such that it was believed to be keeping
le from archery practice. The ban was not
tive, and it continues to this day, though it
w less played than it used to be, Scotland,
North of England, and Suffolk being, perhaps,
last main strongholds. The pitch consists
vo circles or squares of clay, 18 yards apart,
each having in its centre an iron pin, called
"hub," 1 inch of which remains above the
ce. The quoits are iron rings with a dia-
r that must not exceed 8½ inches. The
ht is not fixed, but is often 3 lb. or more.
object of the game, which can be either
gles" or "doubles," is to throw the quoit
or near the hub from the opposite point, 18
s away, one point being scored for each quoit
r the hub than the opponent's quoits, and
being awarded for a quoit that drops over the
called a "ringer." No points are awarded
posing quoits are the same distance from the
and none are awarded if each side has a
r. A game is 11 points in "singles," and 15
points in "doubles." Quoits developed from pitching actual horseshoes, and, to this day, some players make their first practice attempts at it with horseshoes. It is, in fact, to the large-scale disappearance of horses, and, therefore, of horseshoes, from country life that some people attribute the drop in the popularity of quoits. It is interesting to note that, in the United States, horseshoe pitching itself is a game, and one that is still popular.

Shove-Ha'penny. Shove-Ha'penny, an old English game that is still popular, uses a cushioned wood or slate board, divided by parallel lines across it into nine "beds." The "halfpennies" may be actual halfpennies, but are generally round metal discs. The object of the game is to shove the halfpennies into one of the nine beds, the shoving usually being done with the ball of the thumb, though any part of the hand may be used. First turn is decided by shoving halfpennies at the number nine bed, the best attempt winning. A turn consists of five halfpennies, and the winner is the first player to shove three halfpennies into each bed, halfpennies that touch the cushion not counting. Should a player place more than three halfpennies in any bed, his opponent can claim the excess, if he needs them, but cannot win the final point of a game in this way. Push-Penny, a similar game using three coins is played in some parts of the country, mainly in Lincolnshire.

Stoolball. Yet another ancestor of Cricket, Stoolball is still a popular girls' game. The wicket is a board a foot square on a pole 4 feet 8 inches high, the bat has a round striking surface, and the ball is rubber. Wickets are 16 yards apart and eight balls constitute an over.

Pall-Mall. *See* **Old English Games and Customs.**

Parachute Jumping.

Parachute jumping is generally regarded as a last-resort safety measure, to be undertaken only in a supreme emergency, and with considerable anxiety; but it is now also a recreation and a competitive sport, practised entirely voluntarily, and for enjoyment. This form of jumping may be said to have grown out of the Second World War, in which jumping was used to a far greater extent than ever before, and not only for escape in an emergency. Now, international competitions take place, and the sport has an enthusiastic following in Britain.

Parachute jumping as a sport involves jumps of particular kinds, including landings in a certain area, marked by a circle, and demonstrating turns and body control in the air, the parachutist regulating his direction by pulling down the lines of the parachute. Jumps of this kind may be made from about 6000 feet.

The first point that occurs to many people when they think about Parachute Jumping is that it is extremely dangerous. However, those who jump as a recreation maintain that this is not so, and that it is about as dangerous as skiing. Injuries are few and slight, and, in three years, none of the hundred-odd members of the British Parachute Club, of Fairoaks, Surrey, suffered anything worse than a sprained ankle. The parachutes used are so reliable that they still work even if they have been badly packed. A parachute consists of twenty-eight sections, called "gores," each divided into four panels, so that, even if a hole should stretch right across one gore, which is rare, the remainder of the parachute remains intact, and will bring the jumper down safely. As an additional precaution, jumpers wear a small reserve parachute on the chest, but this is hardly ever needed.

Training, which generally takes place at weekends, starts with a period of learning how to fall, how to judge wind direction and speed, and how to pack a parachute. The first actual jumps are from 2,000 or 2,500 feet. Both men and women take part in Parachute Jumping.

Parachutists must be licensed by the Civil Aviation Department of the Board of Trade, and they must produce medical certificates of fitness. Third party insurance is also compulsory, but this is automatically covered by membership of the British Parachute Association. Leading centres of Parachute Jumping are at Blackbushe Airfield, Hampshire; Thruxton, Wiltshire; Manchester; and Gleneagles.

Patience.

Patience is a card game for one person, and, though there are few different games for one, there are countless different forms of Patience. There are some using one pack, and others using two, almost all of them starting with the setting out of the cards on the table according to fixed rules, and having as their object the building up of the four suits on their aces.

The game that might almost be called the basic form of single-pack patience starts with a row of seven cards, only the left-hand one being exposed. Underneath this, and overlapping it, comes a row of six cards with the left-hand one exposed, and so on down to a " row " consisting of only a single exposed card, the exposed cards being left uncovered in each decreasing row. The object is to take out first the aces, and then the cards from two up to king, building each suit on its ace. From the " lay out," exposed cards can be moved when it is possible to put one on a card one pip higher in value of the opposite colour, when any card left uncovered by an exposed card can itself be exposed. The undealt cards can be played three at a time, the top one of each three being " playable," with the one underneath becoming " playable," if the top one is, in fact, played. The undealt cards can be played through three at a time in this manner as often as desired. A slight variation of this game allows the undealt cards to be played through one at a time, but this can be done only once.

Another single-pack game starts with a row of nine exposed cards, with, below it and overlapping, a row of eight, and so on down to one, all the cards being exposed, and the right-hand one being left uncovered in each decreasing row. The remaining seven cards form a separate row at the bottom. The object and the " move " are the same as in the previous game, only one card being moved at a time, and any card being eligible to fill any vacancy that might occur in the top row. Cards in the separate row can be played as required, but, once in the " lay out," they must remain there. This game is called King of the Belgians, and the last seven cards are referred to as the Belgian Reserve.

One to Six is a two-pack game. The player deals out a row of four cards, then discards two to a rubbish heap, and carries on like this until all the cards have been used. If, however, while doing it, he comes across any aces or kings, he takes them out, up to one of each from each suit, subsequently also taking out any that will fit on to these, building up from the aces and down from the kings. Then he goes through the rubbish heap, extracting any cards that will fit on the eight piles. The dealt-out cards, with the rubbish-heap cards, are then dealt again in the same way, the object being to complete the eight built-up suits in three rounds of dealing.

Polo.

Polo, one of the oldest of all games, originated in Persia, then spread in one form or another to China, Japan, and India, eventually being brought from India to England by cavalry officers in the second half of the nineteenth century. Later, it was enthusiastically taken up in the United States and Argentina. Played four-aside, and mounted, on a pitch that should measure 300 yards by 160 yards, its object is to score goals by hitting a 5-ounce ball through goals 24 feet wide with a stick consisting of a long cane fixed at a sligh angle into a wooden or bambo striking head. Th game is divided into periods, called " chukkas, the number of periods varying slightly, as ma be agreed for particular games.

Formerly, Polo was a game for the wealthy, fo it entailed owning and maintaining a string trained ponies. In recent years, however, certai stables and riding schools have provided facilitie for playing and practising Polo, and these facilitie include the hiring out of ponies. This apparentl simple and obvious step is actually quite a revolutionary innovation that has brought Polo withi the reach of almost anyone who wants to play, an thereby increased the popularity of an ancient an exciting game that might otherwise have died ou because of the expense involved.

Pony Trekking.

Pony Trekking as an organised recreatio originated in Scotland in 1953, though somethin similar was known in India before that. Th word *trekking* itself is Afrikaans. Chance an coincidence played a part in starting Pony Trekking, at least on a larger scale than might otherwise have been the case. The first trek was a Newtonmore, Inverness-shire, and was partl organised by officials of the Scottish Council o Physical Recreation. At about the same time, a Aberfoyle, Perthshire, *Rob Roy* was being filmed and many townspeople who came to watch expressed great interest in the horses. This led t the planning of a trek in that area, the organiser of which knew nothing of the Newtonmore venture, though they subsequently heard of it, an received advice from its organisers. The firs trek from this second centre took place in 1954 Now, there are about 70 approved centres, mainl in Scotland, Wales, the West Country, and th Lake District, though there are also some in Ireland and on the Continent. " Approved," incidentally, means that they are inspected ever year by the Scottish Council of Physical Recreation or the Ponies of Britain Club and hold Certificates of Approval from one or other of thos bodies.

Pony Trekking consists of riding over the hill and moors, through forests and along ancien tracks at a walking pace: for, if you ride faste than that, you cease to trek and begin to hack (*se* Riding). No experience whatever is needed, an the complete novice or child who has never ridde at all can enjoy Pony Trekking from the start During the first two days of a trekking holiday beginners will be given some elementary instruction in saddling, mounting, and starting and stopping the horse; and then they will start with shor treks of from five to ten miles.

There are two forms of Pony Trekking, da trekking and post trekking. Most treks are da treks, consisting of circular, all-day tours startin and finishing at the centre. Post treks last fo several days, and include stopping at a differen post or centre each night. There are comparatively few post treks, partly because they are onl suitable for experienced trekkers and partly because of the difficulty of obtaining accommodatio for one night only during the height of the holida season.

The Pony Trekking season is mainly from Ma until September, though some centres are ope from March until December, and there is th occasional one that is open all the year roun weather permitting. Details of approved centre including those especially suitable for childre can be obtained from the Scottish Council Physical Recreation, 4 Queensferry Stree Edinburgh, 2, the Scottish Tourist Board, Rutland Place, West End, Edinburgh, 1; or th Ponies of Britain Club, Brookside Farm, Asco Berks.

Pot-holing.

Pot-holing might almost be described a mountaineering in reverse, for it consists of th descent, perhaps to a depth of 80 or 90 feet or mor and probably by a precarious rope-ladder, of pot es caused by the action of carbon-charged ter on rocks of the chalk or limestone type. :-holing is pursued as a recreation, but it can) lead to extremely useful geographical and logical discoveries, and it certainly does not k danger.

Pot-holes are plentiful in Britain, particularly Derbyshire and Yorkshire, for there are many tances of streams plunging into the earth, to ppear many miles away. While underground, y may alter course considerably, even to the ent of turning almost back on themselves, and y may cross other underground streams. ere many of them reappear, or where many of se that appear start from, is still unknown, for exploration of these underground courses is of nparatively recent origin, and is still far from nplete. It is, in fact, exploration of this type t pot-holers undertake, and, if, in doing it, y subject themselves to considerable dis-nfort and some danger, they also discover a cinating, and even beautiful underground rld. Once below the ground, even quite small -holes often lead to winding passages, tunnels, underground caverns containing icicle-like nations both descending from the roof and ending from the ground. Called stalactites stalagmites, respectively, these sometimes t to form weird columns and pillars, all these other strange formations being caused by cium deposits. Seen in the light of the pot-ers' torches, some of these caverns are wonder-sights, and new tunnels and caverns are ays being discovered.

'or those who have the nerve for it, Pot-holing be an enthralling, and also useful, recreation, it is one that the newcomer should practise y in company with experienced pot-holers, it is one in which the loss of a torch can be a or disaster.

lic School Football.

ll the forms of football popular to-day grew of the games played at various English Public ools a century and more ago. These games ered widely, the rules often depending on ely local considerations imposed by the avail-e space. The Rugby game (*q.v.*) in its modern n is, of course, still played, both at that school far beyond it; and other games that still vive at the schools that originated them are Eton Field Game, the Eton Wall Game, the row Base Game, and Winchester College tball.

ting.

unting consists of propelling a long, narrow, -bottomed boat with a pole, the punter stand-up; and it can be either a pleasant, leisurely eation or a fairly strenuous competitive sport. sporting side is governed by the Thames ting Club, which has headquarters on the mes at Staines in Middlesex. Women, as well nen, take part in competitive events.

unting as a sport has the unique distinction of g confined, not only to one country, Britain, to one river, the Thames; though in some s of the world boats poled from a standing tion are used for various purposes. There e been rumours that Japan has, or had, a lar sport, but these have never been authenti-d.

its. *See* Old English Games and Customs.

e Walking. *See* Athletics, Walking.

kets.

ackets is a fast, racket-and-ball game, played court measuring 62 feet by 31 feet, and using s. A game consists of 15 points, unless 13-all ached, when the non-server can set the game or 5, or 14-all is reached, when the non-server set the game to 3, the game going to the first er to score the prescribed number of points. Only the server scores, the receiver taking over service when he makes a winning shot. When served, the ball must strike the front wall above a line called the "cut" line before striking any other part of the court, but, in play, it may be played either on the volley or after one bounce. If a player impedes his opponent, it is a "let," and the point is re-started.

Real Tennis.

Tennis, sometimes called "Real," "Royal," or "Court" Tennis, is a court game played with rackets and balls that has been called the King of Games, and that was once certainly the game of kings. Henry VIII played, and it is mentioned in Shakespeare's *Henry V*; but the first kings to play were of France, where the game originated.

It is a complicated game, and no description could give anyone who had never seen it an accurate idea of what it is like. Most racket-and-ball games u[illegible]r a net, over which the ball is hit, or walls, against which it is hit, but Tennis uses both. Also, in most racket games, players change ends after so many games, but, in Tennis, they may do so during a game. Matches are in games and sets, a player winning six games completing a set towards the two out of three or three out of five that will make the match.

There are not many Tennis players in the country—there are only about a dozen courts—and very few women have ever played. People who do play, however, most of whom play other games as well, are almost unanimous in voting it the best of all games.

It is said that the term "love," used in so many games to indicate "nought," comes from Tennis, the original French term being "l'œuf," which, in that language, actually means "egg": an egg being, of course, something like the figure used for "nought." This derivation is not sufficiently well documented to be accepted as definite fact; but it is interesting to note that, in Cricket (*q.v.*), the term used for a score of "nought" is a "duck," or, in full, a "duck's egg."

Revolver Shooting. *See* Rifle Shooting.

Riding and Show-jumping.

The almost complete disappearance of the horse from everyday life has been followed by an increase of interest in Riding as a recreation. This is at least partly due to the great attention paid in recent years by both Press and television to one particular branch of horsemanship, Show-jumping. Before learning to jump, however, it is necessary to learn to ride, and many people never go, and have no wish to go, beyond the ordinary, unspectacular riding for pleasure that is called "hacking."

A great deal has been said and written about "correct" riding style, but, in actual fact, there are many different styles. The cavalryman, for instance, bends the leg to some extent; the Red Indian bends it to a much greater extent, more or less in the style that has been adopted by American jockeys; and the cowboy rides with an absolutely straight leg. Yet all these are expert horsemen. To assist in acquiring the normal English style, which is very close to that of the cavalryman, there is an old jingle that is now much less heard than it used to be, but is probably none the less helpful or accurate for that. It runs: "Your head and your heart keep up. Your hands and your heels keep down. Your knees keep close to your horse's sides, and your elbows close to your own." Old or not, anyone who learns it, and then builds up a certain amount of experience of putting it into actual practice is well on the way to becoming a rider.

Those who feel they would like to combine their Riding with something competitive might start with gymkhanas, which are sports meetings that generally include mounted equivalents of such novelty events as obstacle races and needle-threading races. For the more ambitious, gymkhanas could even be the first step towards the top-class competitive sport of Show-jumping.

Show-jumping. A Show-jumping contest is a mounted competition over a circuit of jumps, which the entrants attempt one at a time, each having the field to himself or herself, and being free to concentrate entirely on the jumps, without having to worry about other riders. The jumps, which have to be taken in a certain order, are of many kinds, including fences, double fences, walls, and water. Scoring is by points against, called "faults," so many being debited against an entrant for falling, knocking down an obstacle or displacing part of it, refusing, and other mistakes. Though the event is in no sense a race, there is normally a time limit that must not be exceeded, and, in some events, bonus points are awarded for fast rounds. Show-jumping is not restricted to riders who own their own horses, for some owners do not want to compete themselves, and are only too pleased to let good horsemen take their jumpers round for them. Incidentally, inexperienced riders taking up jumping for the first time will probably find it advisable to make some slight changes in their method of sitting in the saddle. Jumping needs a firm seat, and the novice rider may find it necessary to shorten the stirrups a little.

Allied to Show-jumping, and coupled with it in the difficult three-day competitions, is dressage. This is simply a mounted display revealing that the horse is obedient, balanced, supple, and, in a word, trained; and is a simplified form of the better-known "haute école," or highly-schooled riding. Good riders who seek absolute perfection can, if they are willing to pay for it, take an intensive course of haute école riding and all forms of horsemanship at the most famous of all riding schools, the Spanish Riding School in Vienna. Courses, which are conducted in German, consist of eight hours training a day for six months, and informality is not encouraged, the regulation dress for students being a bowler hat, black jacket, and white breeches. Riders who fall are immediately assisted by an attendant armed, not with a stretcher, but with a clothes brush. *See also* **Pony Trekking.**

Rifle Shooting.

Considered as a sport, Rifle Shooting, which might almost be called the modern equivalent of archery, had its origins in virtually the same conditions and circumstances that had popularised the older weapon five hundred years previously; though, unlike archery, it did not enjoy legislation aimed at abolishing other recreations in its favour. Both were encouraged because, in their respective periods, efficiency at them meant, not only success in competitions, but also the most effective defence in time of war, the great period of the rifle's encouragement for this reason being the latter half of the nineteenth century. Archery as a sport survives to the present day, and Rifle Shooting as a sport continues, though it can no longer be regarded as the most effective weapon.

With a normal rifle, with a calibre of about ·300 inch, competitive shooting is at ranges from 200 yards to 1000 yards, and there are many competitions, the greatest of them being the annual contest at Bisley, Surrey, for the Queen's Prize. Almost equally popular, however, is small-bore shooting, with a calibre of ·22 inch, and this, too, offers many annual competitions.

Revolver Shooting. Revolver shooting, often called pistol shooting, is also a competitive sport, and a very difficult one. Impressions gained from cinema and television screens might lead anyone who has never fired one to think that the revolver is an easy weapon to fire without fuss and with devastating effect. It is the very reverse of this. It is fired, not from the hip, but with the extended arm raised, which is how, in real life, it was generally fired in the old West. It is extremely difficult to hit even a man-size target at 10 yards, and very few people can call themselves good revolver shots, just as few of the old Westerners were good revolver shots. The difficulty is caused by the tremendous "kick" of a weapon that is held, not by both hands and pressed into the shoulder, as a rifle is, but by one hand. Revolvers have sights, but the norm method of aiming is by using the "instincti pointing sense," which is based on the fact tha if you point at an object in the ordinary way, y do, in fact, point accurately. This applies wh pointing a revolver. As with rifles, small-bo target shooting, in which sights are used, popular.

Roller Skating. *See* **Skating.**

Rowing.

Rowing, meaning simply taking a boat out the sea or a river for a short period, is a pleasa recreation and a healthy exercise, but compe tive rowing is one of the most strenuous of sports.

A racing oarsman either rows, which means th he uses one oar, or sculls, which means two oa Races are of various kinds, the best-known bei for crews of eight oarsmen with a cox. Th there are races for crews of four with cox, and f crews of four without cox. There are also even for pairs with cox, pairs without cox, double scul and single sculls. Eights, fours, and pairs ro while double and single scullers, of course, scu In fours and pairs without cox, and in all scullin the oarsmen steer themselves.

Race Rowing is mainly a river sport, but the are races on the sea. For these, crews are usual fours with cox, and they use heavier boats th the normal racing "shell." (*See also* **Boat Race**

Rugby Fives. *See* **Fives.**

Rugby Football.

As its name implies, Rugby Football is bas on the game played at Rugby School in the da when football was not organised and vario schools played to their own rules. The story how the Rugby game originated is well kno and widely accepted, but it is definitely not acc rate and possibly almost entirely apocryphal.

The story is that, in 1823, a boy named Willia Webb Ellis disregarded the rules of that time handling the ball, and that handling was subs quently made legal. In fact, handling the b by catching it was allowed at Rugby before 18 so, if Ellis was responsible for an innovation, was not by handling the ball, but by running wi it after catching it. Running with the b certainly became, and remains, the leading featu of Rugby Football; but the story that Ellis w responsible, though commemorated by a plaq at the school, was first heard years after Elli death, and he never knew of the fame that beca his. He was definitely at Rugby at the tim though, and, a few years later, he played in t first-ever Oxford and Cambridge cricket match.

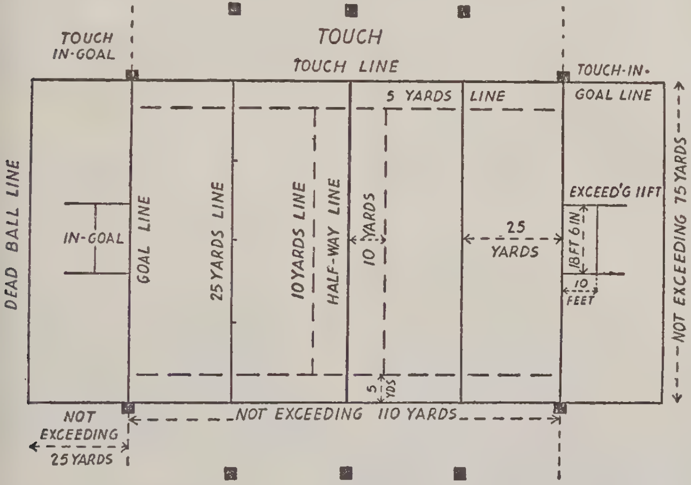
The spread of the game beyond the school th originated it has led to, not one, but two gam of Rugby Football, Rugby Union and Rug League. About twenty-five years after the ga had become organised, with the Rugby Uni as its governing body, there was a dispute on t question of legalising payment for time lost fr work by players. The Union would not agree this, so twenty-two clubs, mainly in Yorkshi seceded and formed the Northern Union, n the Rugby League. Both bodies origina played the same game, but now, after over six years of independent existence, during whi each has made various rule changes, there some important differences.

Rugby was originally played twenty-asi but it is now fifteen-aside in R.U. and thirte aside in R.L., the positions being seven backs a eight forwards in R.U. and seven backs and forwards in R.L. Played on a pitch marked as in the diagram, and with an oval ball, Rug is mainly a handling game, the chief object bei the grounding of the ball behind the opponen

-line. This is a "try," which counts three ts, and entitles the scoring side to an attempt ore a goal by kicking the ball over the cross-from a point measured in a straight line from e the ball was grounded. Other forms of are penalties, which may be awarded any-e, dropped goals during play, and goals a "mark," after a player has signalled a r catch" of the ball during play by shouting, rk." In R.U. goals following tries, called nversions," count two, and other goals three. .L. any goal counts two, but goals from a rk" are not allowed.

e game is started, and restarted after a . by a kick-off from the centre; and, there-, the ball may be advanced by kicking or ing. It may also be passed from hand, but forward. Ball carriers may be tackled and wn down, and they may "hand off" tacklers the unclenched hand. A frequent method tarting after a stoppage is the "scrum-" in which the forwards bend down and against each other, three from each side tuting a front row, and the remainder two uent rows. The ball is then put into the between the front rows, the centre man of the "hooker," endeavouring to gain posses-y hooking it back into, and generally right h, his "scrum." In R.L. this method of ing is used whenever the ball goes out over uch-line; but in R.U. the ball is thrown in t along a "line out" of both sets of ds, unless the side whose throw it is demand mmage. In R.L. kicking the ball straight er the touch-line is allowed only from a ck, the penalty being a scrummage at the rom which the ball was kicked. The effect differences between the two games is .L. is faster and more open, and the ball e continuously in play. A game lasts for minutes, divided into two halves.

ddition to Britain, both forms of Rugby yed in France, New Zealand, and Australia, U. is played in South Africa. Both codes ave other, smaller "outposts" in various ean countries, and there are minor R.U. in North and South America. R.U. is y an amateur game, and R.L. primarily so, though there is a top layer of clubs using part-time professionals.



s:—

■ Indicates Post with Flag. Length and breadth of field to be as near to dimensions indicated as le.

- - These broken lines indicate 10 yards and 5 yards from half-way and touch lines respectively.

al dimensions.—10 feet is taken from the ground to the top edge of the crossbar and 18 inches from inside to inside of the goal posts.

Sailing.

Mention of Sailing tends, perhaps, to conjure up visions of large, graceful yachts, beautiful to see, but clearly to be owned only by the wealthy. Sailing to-day, though, is very different from that. It is mainly sailing in small boats, many of them wholly or partly built by their owners. At first glance the building of a boat might seem a tremendous and highly skilled task, but, in actual fact, it can be as big and as hard or as small and as easy as the builder wishes. Some amateur builders start from the very beginning, acquiring the various materials needed bit by bit, and gradually bringing their boats into being. However, those who either lack the time for this or doubt their ability to construct a boat in which they would feel safe on the water can buy complete boat-building kits; and they can buy them at any stage of construction they choose from hardly started to complete except for a coat of paint. It is more economical to build a boat than to buy one complete and ready for launching, and the earlier the stage of construction at which the owner takes over, the greater the saving. Some owners claim that they enjoy the building as much as the sailing, and it is probably true that the owner who has done some work on his boat, however little, takes more interest and pride in the finished article.

The fact that boat-building is now within the reach of practically everyone means, of course, that the end to which it is a means, Sailing, is also within the reach of practically everyone, for few people are far from some suitable stretch of water. Where there is sailing, there are clubs, which the boat owner can join for quite reasonable fees, and which provide either sheltered moorings or "dinghy parks" where the boat can be kept.

Eventually, the small-boat owner may want to try racing his craft, and there are many events for boats of all classes and sizes. Racing is an enthralling pastime, for, though races are, of course, tests of speed, they are also very much more than that. There is tremendous scope for tactics, and the sport is in every sense a highly skilled one, as well, incidentally, as one with an interesting history behind it.

Skating.

At first glance, ice-skating would not appear to be a normal activity for British people, for it is a part of Winter Sports (*q.v.*), which are possible in Britain only rarely and to a very small extent, and it was formerly restricted to brief periods when rivers, lakes, and ponds were frozen. Despite this, however, the people of this country have always appeared to possess a natural talent for it, and they have practised it whenever opportunity offered. The history of British Skating goes back a very long way, and includes occasions when Skating was possible, and took place, on the Thames, as well as many, more regular instances in the Fen district and other places. In recent years this wish to skate on ice has been catered for by the opening of many indoor rinks, which make the skater independent of weather and daylight, and enable Skating to be carried on throughout the year.

Many people ice-skate just for recreation, health, and amusement, but anyone keen to carry Skating a stage farther and acquire a higher level of skill can find a wide range of opportunities from which to choose. Figure-skating is very popular, and for those anxious to test their skill at it there is a series of medal tests, in which the skater is not in competition with anybody, but is attempting only to reach a fixed standard. Beyond these, there are many competitions and championships. Dancing on skates also attracts many people; and also offers those interested standard medal tests and competitions.

Another popular skating activity is speed-skating, which takes place indoors and, whenever possible, outdoors as well, though the methods and techniques of the two forms of racing differ widely. Outdoors, the skaters normally race in pairs, though each man is timed, and is actually racing against the whole field. Much of the racing is on long, straight stretches of ice. Indoors, skaters race perhaps four at a time, and are directly opposed to those on the ice with them. These races are on small tracks, a lap sometimes being no more than 130 yards. Standard outdoor distances range from 500 to 10,000 metres, while indoor races go from 440 yards to 2 miles. There are also indoor relays, generally of 3 miles, in which teams of four race on the "Madison" method, relieving each other, not at fixed points, but at will. In addition to competitions and championships, speed-skaters also have their standard medal tests.

Ice, however, is not the only surface on which Skating takes place, for, following an unusual history, roller-skating also maintains a large following. Roller-skating was originally introduced long before the arrival of the indoor ice rinks purely to provide ice-skaters with some kind of substitute when no natural ice was available. It progressed by fits and starts, varying from extraordinary "crazes" when it seemed that everybody was roller-skating, to periods when nobody appeared to be doing so. Eventually, it settled down to a steady existence as a popular recreation in its own right that has in no sense been pushed into the background by the increased facilities for ice-skating. The opportunities it offers are almost identical with those of ice-skating, for they include figure-skating, dancing, and speed-skating, with championships, competitions, and standard medal tests in all branches.

Both forms of Skating also offer a team game, and in both it is hockey. Ice-hockey, which is called simply hockey in Canada, where it ori nated, and the United States, is played six-asid with substitutes permitted, and with a rubb disc, called a "puck," instead of a ball. first began to win popularity in Britain soon aft the First World War, and since then has had rath a chequered career, helped forward by the sen professional players from Canada, who play the National League teams, and held back by t lack of facilities for British youngsters to practis for practice sessions mean closing rinks to all t other forms of Skating for certain periods. T game should, however, survive, for there is definite demand for it.

Roller-hockey, generally known as rink-hocke bears a closer resemblance to its parent gam outdoor field hockey, than does ice-hockey. is played with a ball, and is five-aside, with o substitute permitted. Its popularity is such th it is now played throughout the year.

There is a form of hockey on ice that close resembles outdoor hockey. This is Band which originated in England, but is no long played here, though it is popular in Sweden a the U.S.S.R. Some other games have been tri on skates from time to time. One is Badminto which has been played on ice, but only as stage exhibition. Basketball on roller-skates h been tried in several countries, and might w develop and spread.

Skating is not so much a recreation, sport, game as a whole series of different recreatio sports, and games. Each has its following, a while there are enthusiasts who are interested both ice- and roller-skating, or in more than o branch of one or both of them, there are ma ice-skaters who have no interest in or knowled of roller-skating, and vice versa, and many ke supporters of just one branch of Skating w hardly know that the many other branches exi It is, of course, quite possible to take part in bo ice- and roller-skating, and in more than o branch of Skating, and greatly to increase on enjoyment by doing so.

It is not particularly hard to learn to ska It requires strong ankles, a good sense of balan and plenty of confidence; and it is possible start practising, at least to a limited extent, home, for instance, by getting used to standi on skates. Skating is probably more eas mastered when young, but many adults ha successfully taken it up.

Skittles.

Skittles has been played in England since t 13th century and came from Germany where was known as *Kegel*. There are several versio but all consist in throwing a ball down a le alley at a set of pins.

In English Skittles, the ball is a flat-sided obj called a *cheese*; in German and Dutch Skittle round ball is used. Both types of ball weigh least 10 lb. and sometimes as much as 16 Over the years the number of pins has var between 3 and 17, but the normal number is hence the alternative name of Ninepins, though some parts of England 10 are still preferred.

English Skittles, using nine pins, is played in alley about 12 yards long and 3 or 4 yards wi The pins are set up in diamond formation, a players throw the cheese at them fro a distance 6 or 8 yards, being allowed one step forw during the throw. There are several methods scoring. In one, the object is to score 31 in few throws as possible, each pin knocked do counting 1, and any throw in which more than number still required are knocked down counting. Another method is to knock down many pins as possible in a fixed number of thro highest total winning. Yet another allows player three throws in each of a fixed number urns, scoring being 3 if all nine pins are knocked n in one throw, 2 if in two throws, 1 if in three ws, and 0 if any are still standing after the three ws. Pins must be hit by the cheese direct or another falling pin. Pins knocked down by ounds do not count.

he Dutch introduced Skittles, as played with a d ball and nine pins, to America in the 18th ury. The game rapidly became popular but 341 it was made illegal because of the betting t. However, the law specifically mentioned ne pins", so the organisers simply added a h, and the game survived. As Bowling, it me very popular in 1952 when a machine was nted for replacing the pins automatically and e are now over 30 million players in the United es.

1960 this form of the game reached Britain re it soon became easily the most popular ion of Skittles, there now being well over half illion players. There is a British Tenpin ling Association and a Tenpin Bowling Pro- tors' Association of Great Britain. The wls," some of them converted cinemas, offer y of the facilities of a social club. Competent uctors are available at them, and there are tless competitions and leagues.

Whist.

lo Whist is a card game for four players, who nally act independently. Play is as at Whist , but the cards are dealt in threes, the final d being dealt singly, and the dealer exposing ast card to indicate trumps.

ayers then "declare" in turn, starting with player on the dealer's left. The lowest call is propose," which entails making eight tricks a partner, any one of the other players being ble to "accept" in his turn. The next call is lo," which requires five tricks to be made sisted. Next comes "Misère," in which y trick must be lost, and then comes "Abon- e," in which nine tricks must be made. er still is "Misère Ouverte," in which every must be lost with the player's hand exposed, highest of all is "Abondance Declarée," in h every trick must be made. Any player "Pass," and, once a call has been made, callers must make a higher call or pass.

ough calls are made with trumps already nated, certain calls may alter the trumps; with regard to these, there are several views, uite widely held, as to the rules that should y. A player calling Abondance can choose own trumps, though Abondance in the nated trumps—called Royal Abondance— precedence over the same call in another In Abondance one school of thought holds the first round is played on the nominated ps, while another takes the view that the card only is played on the nominated trumps. ther of these circumstances a player making all should not announce his trumps until the l or card has been played, unless it is neces- to announce Royal Abondance to overcall. e is, however, a third view, and it is the view e majority of authorities who have actually en about the game, that the new trumps d be announced before the hand starts. the subject of differing views is Abondance rée, one view being that the caller can e his own trumps, and another that, in this here are no trumps, though both views agree this call confers the right to lead. A good r can easily adapt himself to any of these tions, the important thing being to check versions are being used before starting to On the Misère calls there are no trumps, and in Misère Ouverte the player need not expose his hand until the first round has been played.

Speed-Skating. *See* Skating.

Squash Rackets.

This game is played on the same principle as its forerunner Rackets (*q.v.*) but in a smaller court, with a shorter racket and a rubber ball. It is mainly a singles game, though doubles can be played.

The court has four walls with the rear part divided into two service courts, each having a small "service box" down the court by the side wall. The server must have one foot in the box and serve the ball on to the front wall above the "cut" line (6 ft. in singles) so that it comes back diagonally into the other service court. But it need not land direct, or land at all, but may strike the side wall or back wall or both and be volleyed by the receiver. The object of the game is to score points by striking the ball in such a way that the opponent is unable to return it or make a proper shot. Every shot played in a rally must hit the front wall (directly or via another wall) and must be played on the volley or after one bounce. The service ball must always hit the front wall first. Service proceeds from the two boxes alternately. It is important to note that unlike Lawn Tennis (*q.v.*) services that would be faults become good if taken by the receiver. A game is 9 points but if 8–8 is reached the winner is the next to score 2 consecutive points. Only the server scores points, winning shots by the receiver entitling him to take over the service. Players sometimes accidentally impede each other and when this happends it is a "let," and the point is replayed.

The game enjoys great and increasing popularity. The Central Council of Physical Recreation co-operates with the Squash Rackets Association (the game's governing body) in running courses and there are coaches at many clubs. Though many people play purely for exercise and enjoyment, there are many competitive events, both national and international. Internationally, Squash Rackets is largely dominated by the Egyptians and Pakistanis but a rapid rise in popularity, comparable with that in Britain, has brought Australia very close to the top. The game has developed along slightly different lines in the United States, but with the growth of international competition and the formation of an International Federation the differences from the standard game are likely to disappear.

Surf Riding. *See* Swimming.

Swimming.

Swimming is an extremely popular pastime that also shares with walking the distinction of being a perfect exercise for health, as it exercises the whole body, and can be carried out as easily or as strenuously as the swimmer wishes. It is also a very useful accomplishment that may at any time put its possessor in a position to save a life.

There are several different swimming strokes, the basic stroke being the breast-stroke, now often seen in an alternative method, the butterfly. Faster strokes include the side-arm, the overarm, the trudgeon, and the crawl, but each of these attempts to speed up progress through the water has really superseded its predecessor, and the crawl is now almost universal. There are also two strokes used in swimming on the back, one being a back equivalent of the breast-stroke, and the other a back crawl. It is possible to swim under the water, using the breast-stroke, and to keep the eyes open while doing so. It is also possible to swim down through the water to retrieve objects that may have been dropped.

Ascending through the water is automatic, though it can be hastened by a kick. Remaining stationary in deep water can be achieved either by floating on the back or by treading water, which simply means moving the legs gently up and down.

It is not difficult to teach oneself to swim, and, like cycling, it is an accomplishment which, once learned, is never forgotten. The main thing is confidence, or an absence of any fear of the water. Such fears are quite unnecessary, for water is an element that always tends to keep a human being on the surface, and not to draw him under. Going underneath the water, and staying underneath, requires a definite physical effort, and, if that effort ceases, the swimmer is automatically brought to the surface again. Many non-swimmers who get into difficulties increase these by struggling wildly, for, by doing so, they may easily take and keep themselves under. If they would make only the gentle movements of treading water, they would both stay afloat much longer and present far fewer problems to any swimmer who might be trying to save them.

Saving life in the water is the object of the Royal Life-Saving Society, which teaches the best methods of bringing people who are in difficulties ashore, and also methods of artificial respiration for use in reviving the apparently drowned. Every swimmer should acquire some knowledge of life-saving, for even a strong swimmer may experience considerable difficulty in saving anyone unless he or she has some idea of the best way of setting about it. Many swimmers, for instance, normally use only the crawl and the back crawl, whereas, to save anyone, it is almost essential to use either the breast-stroke or its back equivalent.

Swimming has a well-organised competitive side, with many competitions and championships right up to the Olympic Games. Most races take place in baths, but there are some river and sea events, and the greatest competitive challenge to any swimmer is, of course, the English Channel. Although this has been conquered many times, the swimming of it remains, and will always remain, a wonderful achievement.

Diving. Generally accepted as being akin to Swimming, though actually it is quite a different sport, is Diving. Competition Diving means using boards of various heights, performing certain set dives, and choosing additional ones from an approved list. Diving requires a certain amount of nerve, and also gymnastic ability, including the ability to control the body in the air. Whereas strong swimmers are generally fairly big, divers are often much smaller and more compactly built.

Water Polo. In view of the popularity of Swimming, it is not surprising that there is a water team game, this being Water Polo, in which the object is the scoring of goals, the ball and the goals resembling those used in Soccer, though all shots and passes are, of course, thrown. Throughout a history of nearly eighty years, Water Polo has been beset by rule trouble, and has probably been the subject of more codes of rules than almost any other game. The difficulty is the detection of fouls under the water; the ideal, a game of the basketball type, free of bodily contact.

Surf Riding. Though straightforward Swimming, Diving, and Water Polo are the chief competitive water sports, there are other water activities with large and, in some cases, growing followings, some of them also having their competitive side. Fairly old-established is the Hawaiian sport of Surf Riding, which has been seen though generally in a rather milder form, in many parts of the world. It consists of placing a flat board on the water, and then lying, or, more rarely, kneeling or standing on it, and being carried ashore on the crest of a wave.

Underwater Swimming. Undoubtedly the fastest growing of all swimming activities is Underwater Swimming, which is a link between
ordinary diving and swimming under water, wi
the swimmer, depending on his own lungs, al
to remain below for only a few seconds, and ful
fledged deep-sea diving, with the diver weigh
down with equipment and receiving assistan
from the surface. The underwater swimm
receives no surface assistance, but he does u

Traditional Games and Customs.

Traditional and unusual sporting events
plentiful in many parts of the world, but few h
a longer tradition behind them than the Calci
Livrea that can still be seen, over 500 years a
its inception, in the Italian city of Florence.

version of Football, based on an ancient
k game called Episkuros and the old Roman
of Harpastum. Played twenty-seven-aside
pitch rather smaller than an Association
all pitch, it was originally restricted to the
ity, and in 1672 a game was cancelled when
s discovered that the selected teams included
ers who were only "gentlemen." The
ary people did play, but the game as played
hem was called Calcio Divisi, and was not
rded as the same thing. The playing of
o in Livrea faded out in 1739, but was re-
d in 1898, to stop again in 1902, only to be
red once more in 1930. To-day, there are
rally two games a year between teams no
er restricted to the nobility and representing
our quarters of Florence. They are wonder-
pectacles, for the players, and also numerous
als and attendants, wear fourteenth-century
ume, and the games are preceded by cere-
al processions, and by a special address to
most distinguished person present. The
y for the games is traditionally a white calf.

other ancient Italian sporting event that still
ves is found in Siena, and consists of horse-
g in the city. It is a wild and fierce form of
g in which virtually anything that might
er the cause of victory goes on between the
s. Riding events, many of them of great
uity, figure prominently in countries in
h great horsemanship is an age-old tradition.

st a wall with either the hand or, in the case
most popular form of the game, the Grand
era, with a long, narrow, wicker basket, called a "chistera," that is strapped to the player's hand and arm.

Personal combat sports have always been popular, and Switzerland has a national sport of this type that had its first big tournament in 1905 in Das Schwingen, which means "The Swinging." It is a form of wrestling, in which the contestants, normally very powerful Alpine herdsmen, wear special belts and shorts by which holds are taken. The traditional prize for the winner of the annual Swiss championship is a two-year-old heifer. Iceland has a rather similar form of wrestling, called Glima. Much less similar is the Siamese form of boxing. Competitors in this wear, and use, ordinary boxing gloves, but they are also allowed to use their elbows, knees, and feet, which are bare.

Next, a group of recreations in which the feet are used less lethally, starting with the Netherlands, and the Nijmegen Marches. Over half a century old, these are international long-distance walks that are not races, but reliability trials, in which complete teams must start and finish together within a certain time. The marches take four days, the distance to be covered each day varying between 25 and 30 miles according to the class. Classes catered for include men, women, and also police teams, walking in uniform, and military teams, carrying equipment. The walks, which attract over 10,000 competitors every July, are an unusual and colourful spectacle, and the opening ceremony is as well worth watching as that of the Olympic Games. British walkers, civilian, police, and military, regularly take part. Though called marches, they are really walks; and it is unlikely that many men would consider real precision marching as a recreation. However, women do in at least one country. This is New Zealand, where marching competitions are held between teams of twelve, with a leader, each team wearing a special uniform, and carrying out a three-minute routine to the music of a pipe band. Points are awarded, not only for the marching, but also for the costumes and the leading. Though the competitions are confined to women, teams are generally trained and drilled by men. This type of marching was seen in Britain a few years ago, when the Blair Atholl team toured the country giving demonstrations.

About fifty years old in its own country, Sweden, and quite likely to spread to other countries in the future is Orienteering, which consists of finding one's way about the country from one control point to another by using maps and compasses. Generally carried out on foot, and in wild country, it can also be done on horses, bicycles, motor-cycles, skis, and skates, and in cars and canoes, and in any kind of country, including urban areas. During the Second World War, in which Sweden, though not involved, had to be ready, Orienteering was extensively used in military and civil defence training; and it was then that night Orienteering began, with competitors wearing lamps strapped to their foreheads. Probably the most strenuous annual event in Orienteering is the Swedish three-day mountain race, in which contestants, working in teams of two, have to cover 60 miles of mountains, forests, and swamps on foot, carrying equipment that must include tents and food. Though mainly confined to Sweden, Orienteering has been successfully tried in Canada and the United States, where it acquired its English-language name.

Non-English recreations that English people do not have to travel very far to see are the many and various activities that go to make up Scotland's Highland Games. Highland Games meetings, or gatherings, are sports meetings, but sports meetings with their own definite and extremely colourful and spectacular characteristics. The chief sporting events at them are the "heavyweight" events, including tossing the caber, throwing the hammer in the Scots style, putting and throwing weights of various sizes, and wrestling. In addition, there are competitions in Highland dancing and piping, and often for pipe bands, all playing their parts in a spectacle that can hold its own with any of the many spectacular events that love of tradition and love of sport have combined to produce all over the world. (*See also* **Old English Games and Customs.**)

Trampoline. *See* Gymnastics.

Tug-of-War.

A Tug-of-War is one of the least complicated and one of the most strenuous events in sport. It consists of eight men pulling on a rope against another set of eight pulling in the opposite direction, each team trying to pull the other forward across a line, and each helped by a coach, who instructs them when to "heave" and when to concentrate on resisting the opponents' heaves. A pull may be over in a few seconds, or it may take many minutes. Contests are generally the best two out of three pulls, and a competition may involve three such contests in one afternoon. Competitions may be at "catchweights," which means that there is no weight limit, or they may restrict the eight men to a total weight of, say, 104 stone or 100 stone. The Tug-of-War requires, and will help to develop, great strength.

A popular event that always arouses great enthusiasm amongst the spectators, the Tug-of-War fully merits this position, but it owes some of its success to the fact that it was introduced into the right place at the right time. In the nineteenth century, before athletic sports were really organised, most country sports meetings included events like obstacle races, sack races, and egg-and-spoon races. These, however, though they are found to this day in some children's and local sports, grew less popular, and began to give place to more "serious" ones, favourite replacement for them being the Tug-of-War. Then athletic sports became organised, and the Amateur Athletic Association was founded, and instituted its famous annual championships, including two Tug-of-War championships that still exist, where, a few years earlier, there might have been obstacle-race and sack-race championships.

For years, service units and police forces provided the leading Tug-of-War teams, but, more recently, they have been challenged by teams from big firms. A still later development has been the formation of clubs concentrating entirely on the Tug-of-War. Organisations and clubs with Tug-of-War teams now have their own association, and their own annual championship meeting.

Underwater Swimming. *See* Swimming.

Underwater Watching.

In recent years there has been a considerable increase of interest in the undersea world; and some participation in this has been brought within the reach of those who are unwilling or unable to take part in underwater swimming and diving by the use of glass-bottomed boats, often boats in which the viewer slides back a wooden panel at his feet to reveal the glass viewing panel. Such boats, of course, can only be of use where the water is exceptionally clear and transparent, but, where conditions are suitable, a surprising amount of the life and colour of the world beneath the seas can be seen, and without any of the strain or danger of diving.

Much of the Mediterranean Sea fulfils the necessary conditions of clarity and transparency, particularly, perhaps, the coasts of Corsica, Sardinia, Sicily, and Italy itself. Greek and Egyptian waters are also clear, as are the waters of the Spanish Costa Brava and the Balearic Islands. Going farther afield, there are very transparent waters off parts of the Australian coast, and, of course, in the West Indies.

Volleyball.

Long-established in the United States, and played also in some other countries, Volleyball is a comparatively recent arrival in Britain, where it has been encouraged by leading personalities from the sport of Athletics, who saw in it an ideal game for maintaining fitness, and formed a governing body to organise and control it. A league started in London owed much of its early success to players of nationalities other than British, but the game took a big step forwa when it was adopted by the London Fire Briga as an effective method of physical training.

Volleyball might be compared with Basketb (*q.v.*) in that it is a team game that can be play indoors, though it can also be played on outdo courts. The actual game, however, differs wide from Basketball. Played six-aside on a re angular court that should not exceed 60 feet 30 feet, it consists of "volleying" an inflated b across a net 8 feet high with the hands, the obje being to make it touch the ground in the opponen court, while preventing it doing so in your own

Water Polo. *See* Swimming.

Water Skiing.

Water Skiing originated in the United States the early nineteen-twenties and actually descen from Surf Riding (*q.v.*). Surf Riding led Aquaplaning, in which a board was towed by motor-boat with the rider standing. A furth development saw the board giving place to actu skis and Water Skiing was born. It eventua reached France, and then, in 1950, Britain.

In Britain, it rapidly became popular, par through television, which demonstrated it when was still in its infancy. This led directly to seve new Water Skiing centres being opened up various parts of the country. Britain now h over 75,000 water skiers and there are about hundred clubs, most of them affiliated to t British Water Ski Federation. The Federati which is second in size only to that of the Unit States, is in turn affiliated to the World Wa Ski Union.

Water Skiing has been described as the id family recreation, for, though, at the highest lev it requires great skill and daring, almost anyo including children, can quite easily acqu sufficient skill to enjoy it as a recreation. T more ambitious can, if they wish, proceed to su variations as monoskiing, using only one s slalom, when the skier, generally on one ski, towed through a staggered arrangement of buo jumping, from a ramp between three and six f high; and tricks, which vary from the quite sim to the very difficult. There are Water Ski championships, both national and internation these involve slalom, jumping, and tricks.

The Central Council of Physical Recreat holds Water Skiing courses and there are a coaches at many clubs. Water Skiing can practised in a swimming suit, but many ski wear special rubber suits, or at least jackets.

Walking.

Walking comes so naturally that few peo ever think about it. It is, however, wo thinking about, for it is the basis, not only everyday life, but also of every physical, opposed to purely mental, recreation, sport, a game, all of which involve, if not actual walki then running, which is an equally natural s beyond walking. It is also the basis of traini either for health and fitness or for a strenu sport. It has been said that it is impossible walk too much; and, while those who have d little walking would, of course, have to incre the distance gradually, there is no doubt tha regular, daily two- or three-mile walk would itself prove an effective method of maintain health and fitness.

A great deal of pleasure can be added to walk about the countryside by taking an interest those things which will help you to understand history of this island. The countryside is rich churches, historic buildings, ruins, wayside cros prehistoric camps, and dykes. Besides a g pair of shoes you need a pencil, a notebook 1-in. Ordnance Survey map, a good guide bo and a fund of optimism, imagination, and curios During your rest intervals you can study the m and plan, and read one or more of the many ba ground books to supplement what you have s and stimulate you to further adventure. N only is our countryside full of interest, it is markably varied. Among the organisations wh

ide rambling opportunities are the Ramblers'
ociation, the Holiday Fellowship, and the Co-
ative Holidays Association. *See also* Long-
ince Routes, Section L.

ght-lifting.

eight-lifting is a method of exercising to
ntain health and develop strength; a system
aining that can usefully be at least a part of
preparation for almost any sport or game;
a highly organised and very popular com-
ive sport in its own right. Once, quite
neously, thought to be an over-strenuous and
ngerous" activity, it has now, in more en-
ened days, seen the pendulum swing com-
ely in the opposite direction, with professional
amateur sportsmen of all kinds freely admit-
how much they owe to it, and a large follow-
of seekers after health and fitness, including
en, many of them actresses, models, and
rs whose work demands a near-perfect
e.

hen it is used as exercise and training, the
uousness of it depends entirely on the wishes
e lifter or his or her adviser; for training with
hts does not mean lifting as heavy a weight
ssible, but carrying out a certain number of
itions in various styles with weights well
in the lifter's capacity. For those keen to
lop the maximum strength of which, accord-
to their build, they are capable, weight-
g is certainly the quickest, and perhaps the
way of achieving this. One of the charges
led against it is that it makes one slow, but
is just another fallacy. It does not; and
etitive weight-lifters actually make some of
astest movements known in sport.

a competitive sport, Weight-lifting is
ed into weight classes, and there are many
national and national championships and
etitions. The sport is popular almost all
the world, and has been firmly established in
in for many years.

and-Pulling. Akin to Weight-lifting in that
a method of keeping fit and developing
gth that is also a competitive sport is
d-pulling, using a steel or rubber expander.
ous different "pulls" are possible, and the
gth and resistance of the expander can be
ed at will. Many people use this old-
lished system of exercising for health and
gth; and, for those interested, there are
strand-pulling championships and com-
ons.

t.

ist might be called the standard card game.
s never excited quite the furore of Bridge
but it is long established and popular, both
me and at Whist Drives. It is probably the
ard game, apart, perhaps, from a few simple
s depending on luck, that most people learn,
provides a sound foundation for the embryo
player.

is played by four people, two partnerships
o opposing each other, and with a normal
of cards. The partners sit opposite each
; and the pack is shuffled, cut for trumps,
ealt out singly. The cards are then played
n thirteen tricks of four each, the player on
ealer's left having first lead, and the winner
h trick leading in the next. Ace counts as
highest card—except in cutting, when it
s as the lowest—and it is followed by king,
, knave, and then on from ten downwards.
igher card of any suit takes the lower, unless
rumped by a player unable to follow suit, the
being gathered up by the winner as made.

is necessary to concentrate, to watch the
played, and to endeavour to "place" the
yed cards. This comes with experience, as
n understanding of such unwritten rules as
nd in hand plays low" and "Third in hand
high," and a knowledge of when to dis-
these.

Three-handed Whist is possible, one suit being discarded.

Winter Sports.

There are few fields of recreational or sporting activity to which, given the opportunity, British people take more eagerly than Winter Sports. Enthusiasts from Britain were going abroad to find, and in some cases start, them before the turn of the century; and to-day there are probably a hundred travellers for every one who went sixty years ago.

Switzerland is, of course, the traditional objective, but there is actually a wide choice, for facilities exist in Norway, Austria, Italy, France, Germany, and Czechoslovakia. There are opportunities to suit most purses, and to suit both those who want only sport and those who want sport combined with entertainment. If the object is simply Skiing, the most popular of the winter sports, there is really no need to travel further than Scotland, which provides excellent facilities, and is increasing these every year.

For those whose time and experience are both limited, skiing is normally of the downhill variety, rather than the lengthy journeys on the level as well as on hills, and up as well as down, at which many Continental, and particularly Scandinavian, skiers are adept. Greatly increased facilities in the way of ski-lifts enable the holiday skier to work in three times as many descents as the skier of only a few years ago. Almost every resort has a ski-school with an English-speaking instructor, and it is always advisable for a novice to join this. It is also advisable for novices to start training for a ski holiday some time in advance, both by ordinary physical training and by attending a dry ski-school. The air in winter sports resorts encourages more activity than is good for a completely untrained person, and the fitter the skier, the less his chance of being injured. Skiing accidents are plentiful, but many of them could be avoided by the exercise of a few simple precautions. Having lessons is one; being fit is another; short skis with safety bindings are still another; and refusing to ski late, which may be any time after four o'clock, is yet another, for, as the light fades, it is replaced by a bluish light that makes uneven patches difficult to see, and the snow tends to ice over. Most winter sports equipment can be hired, but hired or bought, and regardless of the extent to which fashionable skiing clothing may be advertised, the most important items are the boots. The winter sports season lasts from December until March, but the snow is sometimes late, and, while Christmas and New Year should be safe enough, February offers the certainty of snow, combined with longer days.

Ski-jumping is a separate sport, and one for experts. The jumper takes-off down a steep slope and over a platform, which he leaves at a speed of about 50 m.p.h., to land something like 150 feet below his take-off, and more than that distance out in front of it. Ski-Joring is really ski-racing behind unridden horses, but the term is also applied to quite gentle ski-trips behind ridden horses, horse-drawn vehicles, and mechanical vehicles.

The Biathlon is a combination of skiing over a 20-kilometre course and rifle-shooting. There is a World Championship, and Britain enters for this, but the leading exponents of this sport are the Scandinavians and the Russians. As with the Modern Penthathlon (*q.v.*), most British competitors are servicemen, but the sport is in no way barred to civilians.

Bobsleigh Riding and Tobogganing consist of riding and racing down ice runs at terrific speeds on sleighs, the bobsleigh being for two, four, or five riders, and the toboggan, which takes its name, not from anywhere in Europe, but from a Red Indian language, being for one rider. Bobsleigh crews sit, the first man steering by a wheel or ropes, and the last man operating the brake with which the sleigh is fitted. Toboggan riders lie face downwards, and brake through special spikes on their boots. Both sports are exceptionally thrilling, and both can be dangerous.

Even greater speeds, ranging from 50 to 100 m.p.h., and even greater danger, are to be found in Ice-Yachting. This sport, or something very like it, has actually been known for hundreds of years, but it is now rarely available in Europe because of the lack of frozen lakes large enough for the modern high-speed yachts. In the United States, however, there are over 3,000 such yachts to be seen during the season, which, as with European winter sports, lasts from December until March. One-man ice-yachts normally carry about 75 square feet of sail, but two-man yachts may carry as much as 650 square feet. Two-man yachts may be 56 feet long and weigh half-a-ton.

At the opposite extreme from the point of view of speed is the 400-year-old Scottish game of Curling, which is played on ice, but not on skates. It resembles Bowls (*q.v.*), but the implements used are curling stones weighing about 35 lb., and having handles. Slow, but still-moving stones are encouraged by sweeping the ice in front of them with brooms.

Not a European winter sport, but nevertheless a snow sport in Canada is Snowshoe Running. Like skiing, this is a useful method of travelling about on snow that has been made the subject of races. The Canadian side of the Atlantic is also the home of Snow Snakes, a Red Indian game that consists of throwing a polished wooden stick along an ice trough in the snow. These "snakes" have been known to go for over a mile and to travel at 120 m.p.h. (*See also* Skating.)

Wingfield Sculls. *See* **Boat Races.**

Wrestling.

Wrestling, an individual combat in which competitors, using only their bare hands, endeavour to throw each other, is one of the most natural sports, and also one of the oldest. It is practised in many countries, and in many different styles, in most of which the wrestlers are divided into classes by weight.

In Britain, probably the most popular style is Catch-As-Catch-Can, in which the wrestlers start apart, and may try to throw their opponents by grasping them with the hands or by various kinds of trip. During the bout, the competitors may be either on their feet or down on the mat, and the rules contain various provisions to prevent the bout lasting for an indefinite time. Wrestlers reaching a deadlock on the mat may be ordered to stand up and start again, and points decisions after a certain time are also possible. Certain dangerous holds are barred.

Another style is Cumberland and Westmorland Wrestling, which is extremely popular in those counties, and in Scotland. In this, the wrestler clasps his hands together behind his opponent's back, and all throwing is done by the legs, the breaking of the opponent's clasp constituting the fall. The initial hold is, therefore, of major importance, and the taking of it often takes longer than the actual bout.

A further form of British wrestling is Cornish Wrestling, in which the wrestlers wear canvas jackets, by which all holds are taken. A similar form of wrestling is found in Brittany.

In Græco-Roman Wrestling, which has always been very popular on the Continent, though less so in Britain, wrestlers start apart, and may take hold only above the waist. Bouts in this style may take a considerable time. At one time, there were many Græco-Roman handicap matches, in which a top-class wrestler undertook to win a fall, or a number of falls, in a fixed time.

Græco-Roman was formerly the style used
professional wrestling, but, in recent years, p
fessionals have used the "Free" or "All-I
style. This has rules, but it is not always v
clear just what they are, and this, combi
with widespread suspicions that bouts are
really genuine contests, has led to the quite la
following that it retains going to see it more
an amusing "stunt" than as a serious sporti
event. In the United States efforts to wid
interest in it have taken the form of staging bo
in a ring that has been turned into a sea of mu
or that has been filled with fish. All this has,
course, done considerable harm to the reputati
of what is really a fine sport and a healt
exercise.

Judo. Wrestling has been popular for centur
in Oriental countries such as India, China, a
Japan. Of the various styles, one from Jap
has won popularity in many countries, includi
Britain.

This is Judo, which derives from the mo
elaborate Ju-Jitsu. Governed largely by ritua
and with wrestlers graded according to abili
Judo is now an international competitive spo
but it is still often taken up as an effective meth
of defence against a stronger or better-arm
attacker. Requiring a knowledge of anatomy,
consists partly of defence by knowing how to f
and partly of attack by locks which give t
opponent a choice between capitulation and
broken bone, and by paralysing nerve centr
The various locks are potentially dangerous, an
when practising, should be released immediat
the opponent requests this. Also developed
Japan, though it originated in China, is Karate,
combat system so potentially dangerous th
when practised as a sport, attacking moves mu
only be indicated, and never pressed home.

Yachting.

The first recorded sailing contest was a ra
from Greenwich to Gravesend on 1 October 16
between Charles II, who won, and his broth
the Duke of York. In those days, such conte
generally took the form of manœuvring for po
tions of advantage, rather than straightforwa
racing, for the Royal Navy also relied on saili
and every privately owned vessel was a poten
ally useful naval auxiliary: a fact that emphasi
the appropriateness of the right of Englan
most famous yacht club, the Royal Yacht Squa
ron, to fly the White Ensign. The club w
founded as the Yacht Club in 1815, becoming t
Royal Yacht Club in 1817, when the Prin
Regent joined, and taking its present name
1832. In 1851 the club put up for competiti
a silver cup that has become the most famo
trophy in yachting, and one of the most famous
sport. In that year a schooner of the then famo
New York pilot-cutter type, called the *Ameri*
sailed across the Atlantic to compete in a 53-m
race round the Isle of Wight for the new cu
capturing the trophy which now bears her name

To date, there have been nineteen challeng
sixteen by Great Britain, two by Canada, and o
by Australia, but not one of them has succeede
Britain's 1958 challenge, which was the seve
teenth, pointed the present trend in yachti
which is towards smaller vessels. Previously, t
America's Cup conditions stipulated that the ra
must be between very large yachts of the "J"
21-metre type, and that, if the challenge was fr
across the Atlantic, the challenger must s
across. In 1958, the rule about sailing across t
Atlantic was waived, and the event was betwe
yachts of the 12-metre class.

Large vessels are still seen in the famous B
muda Race, but the modern trend is very evid
in the growing popularity of the annual Folkest
Dinghy Race across the Channel, which also h
a class for catamarans, very fast and very popu
boats that consist of two boats side by s
joined by a kind of raft.

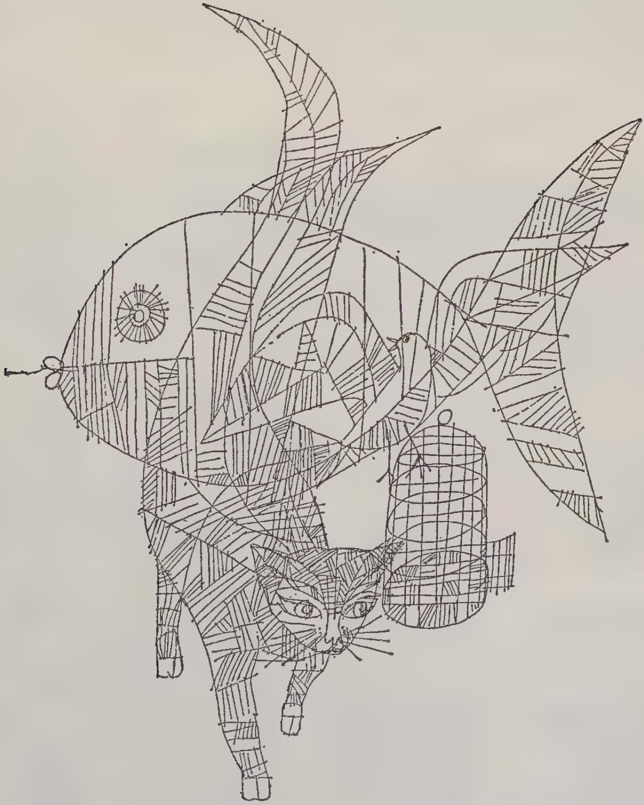
DOMESTIC PETS



DOMESTIC PETS

By ALASTAIR N. WORDEN, M.A., (Cantab)., F.R.I.C., formerly Milford Research Professor in the University of Wales.

This section attempts to deal not with all the many hundreds of animals that may be kept as p but only with those that are best suited to average homes in Great Britain. The maintenance monkeys, squirrels, bats, mongooses, and snakes, while quite feasible to those with experience facilities, requires considerable time and—in some instances—expense. Those who contemplate s exotic pets should consult works of reference, study the methods adopted in zoological gardens, discuss the matter with experts. Even in the case of the more common animals, the informat provided in the following pages is to be regarded only as a beginning, to be supplemented so fa possible by practical experience, discussions with more knowledgeable owners, and the study of m detailed writings.

Certain considerations are basic. Never keep a pet unless you are really interested in it and prepared to give it due—and regular—care and attention. Don't keep a pet you cannot afford maintain in health and comfort. Scrupulous attention to cleanliness is essential, and wise feedin one of the most important factors in avoiding illness and loss of condition.

Since the passing of the Veterinary Surgeons Act of 1948 it is illegal for anyone to practise diagnosis and treatment of animal diseases unless he or she is: (1) a veterinary surgeon; or (2 person whose name has been placed on the Supplementary Veterinary Register. (Certain employ of Animal Welfare Societies are specially licensed, but it is intended that in future all animal treatm shall be given by or under the direct supervision of members of the veterinary profession.) Not e a pharmacist may attempt to diagnose or treat an animal. Anyone may, of course, render "f aid," and an owner may—at his or her own risk—apply treatment. It is, of course, a wise precaut to seek veterinary advice for any ailing animal, and the sooner it is sought the more likely it is t good results will follow.

BREEDS AND VARIETIES OF DOGS.

Of recent years, dog-breeding and showing have become specialised occupations, which average people cannot be expected to take up without having adequate time or resources at their disposal. Any amateur who wishes to breed for profit from pedigree animals should most certainly seek expert advice before attempting to do so.

Dogs which are intended for show or for pedigree breeding must be registered with the Kennel Club, 1 Clarges St., London, W.1. The requisite forms and regulations may be obtained on application to the Secretary.

The breeds of dogs recognised for the purpose of separate Registration and Stud Book entries by the Kennel Club are:—

SPORTING BREEDS.

Afghan Hounds
Besenjis
Basset Hounds
Beagles
Bloodhounds
Borzois
Dachshunds
Deerhounds
Elkhounds
Finnish Spitz
Foxhounds
Greyhounds
Harriers
Irish Wolfhounds
Otterhounds
Salukis
Whippets

Gun-dogs.

Penscher Miniature

the limited space available it is impossible
escribe the special characteristics of the
rent breeds. The breeds recognised in Great
in are subject to constant review by the
el Club, and it is probable that the number
continue to be added to from time to time.
e dog was probably the first animal to be
esticated in the true sense of the word, and
ses to which he has been put by man are
st legion. Throughout the world dogs are
oyed to help protect herds and flocks, and
d the dog trained for shepherding plays an
ral part in sheep management. The names
ound, Deerhound, and Otterhound all
ate the specific uses to which dogs have been
n the Chase. Greyhounds and Whippets are
in coursing, and work singly or in pairs,
r than in packs. As their names indicate,
arious Setters and Pointers are employed to
ate the exact whereabouts of game, and
iels also are widely used as gun-dogs. The
uses to which dogs have been put in field
s include hunting over rough and difficult
try by small terriers, and going to earth to
or hold badgers, foxes, and otters. Fox
ers, Dachshunds, Dandie Dinmonts, and
ish Terriers are among the types which have
so employed. Dogs have played their part
n entertainment: thus there are performing
notably the Poodle, and racing Whippets and
hounds, while in former times various types
hting, including the baiting of bulls by Bull-
were to be seen. The use of sledge-dogs is
known, while in Belgium and elsewhere dogs
at one time widely used as traction animals.
aching days, the Dalmatian was a carriage
and modern scientists have recently sug-
d, as a result of experiments, that the
on under or behind a coach which a Dalma-
automatically takes is determined by hered-
Perhaps the most exacting use to which
has ever put dog was in China, where the
-Chow was once maintained as a source of
and fur! In Portugal, fishermen employ a
of dog to accompany their fleets. The dogs
estion (Portuguese Water Dogs) will dive
he sea to retrieve a broken net or an escaped
nd will even swim from one smack to another
vey messages! In New Guinea native dogs
s scavengers, while in various countries on the Continent of Europe "truffle dogs" are employed to locate the fungi known as truffles, relished as a table delicacy.

The above paragraph is far from exhaustive, and for those who wish to know more of the characteristics of the different varieties of dogs, reference should be made to such volumes as *Book of the Dog* by Brian Vesey-Fitzgerald (Nicholson and Watson, London; 2 guineas) or *Working Dogs of the World* by C. L. B. Hubbard (Sidgwick and Jackson Ltd., London; 16s.) For general guidance on dog management, see *The Right Way to Keep Dogs* by R. C. G. Hancock (Elliott, Kingswood, Surrey; 5s.)

For present purposes it is, however, as a pet or companion that we are considering the dog, and it must be agreed that many of the most successful animals for this purpose are cross-breeds or "mongrels." There are many fallacies or unsubstantiated generalisations regarding the relative merits of pure-breds and mongrels. This is in fact an intricate scientific problem, and probably the simplest way of summarising the true position would be to say that, from the point of view of health and temperament, there are good, bad, and indifferent specimens among pure-bred and cross-bred animals. It is true that within a breed (or within a local community of mongrels for that matter) certain weaknesses or undesirable traits may arise from hereditary defects.

It may be noted that the word "dog" is applied to the whole species, although it is used also to denote the male as opposed to the female, for which the correct term is "bitch." Young animals are referred to as "dog puppies" or "bitch puppies" respectively. A male animal employed regularly for breeding is known as a "stud dog," and the corresponding female as a "brood bitch." In hunting circles the Foxhound is referred to as a "hound," and the term dog and bitch are employed only as prefixes to denote the sex.

CHOICE OF DOG.

However attractive the idea of keeping a dog may be, it is unwise and unkind to purchase or to accept one without very careful consideration. Dogs require regular feeding, grooming, and exercise and, if they are to be allowed to show their full capabilities, constant companionship and attention. Nothing is more pathetic than the unwanted dog, which may have been purchased because of a passing whim, and with which no one appears to have the courage to part. If, on the other hand, one is prepared to give all the necessary time and trouble to the proper care of the dog, the reward will be ample.

The size of the choice is important. Many people keep dogs which are far too large for their houses and for their purses. The smaller the dog, the less food, exercise, and house-room will he need, and the many varieties of terrier provide a range from which suitable choices for most households may be made. In any event, a very large dog should not be chosen unless expert advice has been taken about his feeding and other requirements.

Household dogs of six months of age or over must be licensed. Licences may be obtained from any post office (7s. 6d. at present).

MANAGEMENT OF THE DOG.

Accommodation.—Up till comparatively recently most dogs were kennelled down out of doors. This practice has its advantages, but today the majority of pet dogs are allowed more or less the run of the house. A warm sleeping-place, such as a box or basket, should be provided, and should contain removable bedding. Newspaper is an excellent non-conductor of heat. It is a very useful material to place at the bottom of a dog's box; and on two or three thicknesses may be placed a rug or blanket on which the animal may lie. It is astonishing the amount of grit and dust a dog can bring into a house on his limbs and the lower part of his body. His bedding will require frequent shaking out and renewal, and paper is easily changed. The box or basket in which the dog lies should be allowed a place free from draughts, and requires airing daily when the dog leaves its bed in the morning. Wood-wool makes excellent bedding in outhouses or where a special structure is provided by way of dog-kennel, but is inclined to be messy about the house, as a dog will draw portions of it about the room as he leaves his bed. If straw is used, it is best stuffed into a sack and made into a kind of mattress. An odd piece of linoleum forms an excellent foundation to the dog's sleeping-box or kennel; it does not strike cold to the skin, is a slow conductor of heat, and has the advantage of being easily kept clean, particularly during illness, when there may be discharges and messes to be frequently cleaned up, until the animal can once more go out of doors.

Exercise.—Every dog should be exercised regularly, but there is no need to over-exercise, and the practice of allowing a dog (other than a large and athletic animal) to run behind a bicycle for mile after mile cannot be too strongly deprecated. Two or three fairly short walks a day are sufficient for a small terrier, always provided that there is a garden in which he can play on fine days and some open space where he can run freely for a short time. While still in the puppyhood stages, a dog should be trained to walk to heel and to beware of traffic. Even so, it is usually safer to put him on a lead in busy thoroughfares. One point which, to the annoyance of the public, many dog-owners fail to realise, is that their animals would show much less tendency to fight if allowed to investigate one another off the lead. A dog naturally feels aggressive if put on the lead immediately a rival hails in sight. There are, of course, certain dogs which attack others at sight; these are a public nuisance, and should never be allowed loose on the streets.

The practice of allowing a dog to take his own exercise is to be deprecated, especially in towns and suburbs. The animal will be tempted to sniff into dustbins, and, if a male, will tend to follow a bitch in season or to take part in the unsavoury "dog parties" which are so often to be seen. Furthermore, such an animal is usually responsible for the disgusting habit of fouling the pavements and gateways. In this connection, it should be emphasised that dogs may quite easily be trained to defæcate in the gutter, or on the grass verge, and so avoid contamination of the pavement or carriage-way. In some districts owners are liable to a fine if their dogs foul the pavement.

Training.—Patience combined with the gift of putting yourself in the dog's place is the chief requisite for successful education. It is most important to encourage regularity of habit, as an animal will obviously learn very much more quickly if his daily walks, meals, and grooming take place at fairly constant times. A quiet firmness is the ideal method, and a puppy should learn early that a command *is* a command, and must be obeyed. There is no need to shout and make an exhibition of oneself, or to race in circles after a disobedient puppy; if these things are done, the animal will never become so well trained as it otherwise would. Again, it is rather ridiculous to chastise a puppy *after* he has somewhat belatedly decided to come to heel; quite obviously, he will then be liable to think that he has done wrong in actually coming to heel. Whatever happens, it must never be that the dog becomes master; there is no more unbecoming sight than that of a person with a frankly disobedient dog, and if the animal be large and powerful it may prove a menace to its owner and to the public.

Puppies should be house-trained at an early stage. If care and thought are given to the matter, the animal will soon learn not to make messes in the house. However, it is very stupid to forget all about a puppy or dog for many hours, and then, out of sheer vexation, chastise it for having made a mess. If puppies are let out every two hours or so at first, they will soon learn not to make a mess. Encourage them for performing in the right place rather than scold them for doing so in the wrong one. Physical punishment should be administered only where strictly necessary, and then in a sensible fashion. The most effective
method is to grasp the dog or puppy by the s
of its neck and to shake it.

Grooming and Washing.—Whilst short-hai
breeds need little or no attention to the coat,
an occasional brisk rub down with a brush
rough towel (which incidentally puts a pleas
gloss on the smooth-haired breeds), yet with
long-haired breeds grooming should be carr
out regularly, and if the habit is made a daily
it will not be forgotten so readily. Nearly
dogs love this procedure, and most dogs
actually ask for their daily groom by jumping
the table or bench on which it is carried
Steel combs and brushes are sold by many sho
principally corn chandlers, though some st
chemists also provide a suitable range of groo
ing kit for all breeds. There is a curious fet
current among many breeders that dogs sho
not be washed. There is no reason why, wit
few simple precautions, a dog should not
washed whenever it is socially necessary. T
first precaution is to use a soap that does not c
tain an excess of soda. The strong washing-
soaps, excellent as they are for certain purpo
are too irritant for a dog's skin. While so
of the toilet soaps suitable for human use may
employed for dogs, the special dog soaps
shampoos are much better for the purpose. Th
are more suited to the dog's skin and coat,
have better detergent properties. It is import
not to have water that is too hot—as with
baby's bath, it should be possible to dip the po
of one's elbow into the water and find that
gives a pleasantly warm sensation but is eas
bearable, *i.e.*, it should not be above 95–100
On emerging from a bath a dog will shake hims
thoroughly, and then, if not curbed, will roll
the floor or ground and speedily cover hims
with dust or dirt! It is therefore necessary
give him a brisk rub down with old (but clea
towelling, whereupon he may be allowed to
off in a warm place free from draughts or, in go
weather, put on a lead and taken for a brisk wa
In the case of many of the long-coated breeds
is customary to have them trimmed at the beg
ning of summer, and this is a sensible precaut
that may avoid a good deal of distress during
weather. The smaller long-haired dogs
particular, such as Scottish Terriers, suffer undu
from the heat if their coats are grown too long.

FEEDING OF THE DOG.

Meat, usually beef, is generally regarded as
staple article of the dog's diet. It must
pointed out, however, that although the dog
naturally a carnivore (flesh-eater), ordinary m
(muscle or "flesh") is not a completely adequ
diet, and lacks certain factors which the wild
would find in the blood, bones, liver, and ot
organs of his prey. Furthermore, it has be
proved scientifically that dogs can thrive on
meatless diet. In spite of these reservatio
however, meat must be regarded as an excelle
article of food, and if properly supplemented
prove very satisfactory. In recommendatio
which have recently been made in America (
S. R. Speelman, of the U.S. Department of Ag
culture) it is suggested that meat (beef, lam
mutton, or horseflesh, providing that the last
fed regularly and not spasmodically) or m
substitutes (fish, milk, eggs, etc.) should c
stitute one-half of the daily ration, and that
remainder should comprise approximately eq
parts of cereal substances (bread, biscuits) and
vegetables (carrots, spinach, onion, beet, et
It is pointed out that many dogs do not accept
vegetable material readily. On this basis,
approximate quantities of food required by ad
dogs have been calculated as follows:—

Weight of dog.	*Total food per day.*
1 lb.	2 oz.
10 lb.	12 oz.
25 lb.	1½ lb.
50 lb.	2 lb.
75 lb.	3½ lb.
100 lb.	4¼ lb.
150 lb.	5¼ lb.
225 lb.	7 lb.

Weights of up to 10 lb. would include the toy eds, 25 lb. would correspond to a Fox Terrier; edale Terriers and Retrievers would fall into 50–75-lb. class, and the larger weights would those of the very big breeds, such as the St. nard.) The quantities given are, of course, *pproximation* and no more. Dogs which lead ery active life will require more, while those ch take little exercise, or which tend to put on easily, will require less. Common sense is essary, and great care must be taken not to r-feed or to under-nourish.

eat is probably best fed raw, or lightly cooked, many animals appear to have a preference bably through habit) for well-cooked meat. any event, the meat should not be "over-e," as there is substantial evidence that longed heating destroys much of the food e of the meat protein. *Fish* is an excellent stitute. There need be no anxiety about the d with which a dog swallows lumps of meat also neglects to masticate them. The teeth e dog are for tearing meat, he is not concerned biting his food up small; indeed, his salivary ds contain no digestive ferments, as is the with some other animals.

ilk is almost essential during pregnancy and ation (see below), and may well be included normal dietaries. Whether or not *bones* ld be fed is a matter which has been hotly ated, but for mature household dogs the lence suggests that they are unnecessary. e teeth of racing greyhounds, which receive a oppy" diet, are quite as good as those of the rage household dog.) Bone-feeding is respon- for much trouble, including constipation, al impaction of the rectum, and lodgement ieces of bone in the mouth or throat. The e of bones is, of course, that they contain e quantities of essential mineral substances, for this reason the inclusion in the diet of e-meal, or of steamed *bone-flour*, or, preferably, ineral supplement, is recommended. Only small quantities of these substances are ired.

read is an article of food which is often over-ed in the case of the dog, but there is no bt that wholemeal bread is very suitable ed, provided it is not fed to excess.

he answer to the question whether a dog ires vegetables is, in the main, no. From the min C standpoint they are quite unnecessary, e it has been shown that a dog manufactures vitamin for itself, but the fact remains that y dogs, particularly of the toy variety, enjoy w slices of banana or apple, and there is no n in letting them pander to their taste. etables do help, however, to provide roughage, cooked (*not* raw) *potatoes* may be used in place read or biscuits. The dog—like many other nals—cannot digest raw starch properly. *ced maize* and *oatmeal* are other substitutes, but ust be remembered that the energy value of e is high and that the dogs must never be fed. *Dog biscuits* are an item that were long isfavour with some professional people on unt of their often having been made from ised white flour (see section on Canine teria), but now that this factor has been over-e, and the biscuits themselves are being im-ed in other ways, their use for the non-meat ion of the diet may be recommended.

ean fresh *water* must be provided at all times. addition to the diets recommended above, e are on the market several tinned dog foods h claim to be complete, or almost complete, for the dog. It must be said that many (including those of the writer) have remained xcellent health when receiving one of these s as a large part of the diet over long periods. e is, therefore, little that may be said against widespread use of the better varieties of such ucts. Again, it is a matter for common e; if an owner finds that his animal is thriving ich a diet, he is wise to continue to use it.

is customary to give dogs two meals a day. e is no need to give more than two to healthy ts, for the dog's stomach is exceedingly cious and adapted to long gaps between s. Many dogs thrive on only one meal in ty-four hours. Whatever plan is decided egularity should be adhered to, and a meal eals given at the same times every day. Dogs require vitamins A and D and B complex. There are several ways of administering these, but the special commercial preparations, including the modern form of condition-powder tablet, are the most convenient.

The *pregnant* and *lactating bitch* require special consideration. The food requirements are very much increased in a bitch which is carrying puppies, especially towards the end of the period. Normally, appetite is not a complete guide to a dog's food requirements, but in pregnancy and lactation the bitch must not be allowed to go hungry. It is quite normal for a heavily pregnant bitch to require over one and a half times her normal amount of food, and in lactation her requirements will increase still further. Milk is a most excellent article of diet at this time; indeed, there is no better way (apart from commercial preparations) of replacing the milk which the bitch is giving to her own puppies.

Up to the age of three weeks or so, *puppies* need have mother's milk only, but at any time after this it is a sound policy to give them additional food, and so spare the mother and also render weaning (at from six to eight weeks) a *gradual* process. At first a little cow's milk or one of the commercial "dog-milk" preparations may be given, and gradually the puppies should be encouraged to eat solid food. Eggs (if they can be spared), wholemeal bread in milk, or even finely minced meat may be given, at first in very small amounts but later in larger quantities. If this process is carefully carried out, there will be far less trouble at and after weaning time. After weaning, puppies should receive five or six meals a day, and this number may be cut down gradually until two or three only are given to the fully grown dog. (The smaller breeds are fully grown at about a year.) *More* meat or meat substitutes and milk, and *less* cereal or vegetable matter, should be fed to the growing dog as compared with the adult. This fact is important, as the substances present in meat and milk are required for laying down the growing tissues. Nevertheless, the energy portion of the ration is important, and the cereal or vegetable should be nutritious and not fibrous. It is possible to rear puppies by hand from birth if the bitch for any reason should die. It requires great patience for the first two or three weeks, as naturally the puppies will require feeding once or twice during the night. Special milks for puppies are to be recommended. Cow's milk requires enriching with fat and sugar to approximate to the composition of bitch's milk. Feeding will have to be done at every two or three hours, and a very useful gadget is a fountain-pen filler attached to cycle-valve tubing. Very small quantities are required for the first two or three days, and a level teaspoonful of milk is more than sufficient for the average terrier at first. Even with the best care in the world hand-fed puppies tend to be weaklings and do not grow as fast as those naturally fed. A foster bitch, if obtainable, is much to be preferred.

BREEDING OF DOGS.

It is natural for adult dogs of both sexes to wish to breed, and in the case of the female especially it is an excellent thing if one can arrange for a suitable mating to take place. Bitches come "into season" or "on heat" (lay terms for œstrus) at approximately six-monthly intervals, but it is not advisable to breed from the first season which occurs usually at about eight to nine months of age, but over a wide range of age according to breed and other factors. The periods of season often occur between January and March and in early Autumn, but there is no fixed rule. Each season lasts for three weeks. For the first seven days, approximately (pro-œstrus), a bitch does not permit mating, though during this time she is a source of strong attraction to all males in the neighbourhood. At about the seventh to the tenth day the blood-stained discharge, which ushers in the heat, stops; this is usually taken by the breeder as an indication that the bitch will stand to service. If possible, it is always better when puppies are wanted to allow mating to occur more than once. Under natural conditions a dog and bitch are usually strictly monogamous and mate for life, and during the period of œstrus will mate many times. A dog and bitch that are kept together all the time will probably behave naturally, but under domestication both dogs and bitches usually become promiscuous. Many bitches will in fact accept service from different males on different days, and the phenomenon of superfecundation, *i.e.*, the production of a litter that is fathered by *two* males, may occur. It is therefore wise to retain strict control of the bitch throughout the whole of the three weeks or so she is in season. At the end of season the bitch passes into a state of "metœstrus" if she has not conceived.

If a bitch conceives, she carries her puppies for a period of about nine weeks. There is, however, a normal variation of fifty-eight to seventy days, and puppies born before the fifty-eighth day sometimes live. The number of puppies born varies with breed; in the smaller terriers it is usually from four to six, but in Airedales and Alsatians the number may be eight to ten, and the larger breeds tend to have even more offspring at a time. Birth usually takes place fairly easily in the larger breeds, but there is often much difficulty in the case of the short-legged breeds, such as Scottish and Sealyham Terriers, Pekingese and Dachshunds. In some breeds, in fact, the problem is one that is giving serious concern to veterinary surgeons and breeders.

A short while before her puppies are due, a bitch will "make her bed." Owners are often amazed at the destruction of soft furnishings, or even of wall-paper, that a previously well-behaved bitch may carry out at this time; it is therefore by far the best to provide a suitable box (if the animal has not one already). A smooth flooring such as a strip of linoleum serves for the bitch to give birth to her puppies. Her instinct to tear up everything given to her for bedding may lead to suffocation of the puppies by pieces of bedding. Provided labour occurs in a warm room, it is sometimes better—according to the temperament of the bitch—to remove each puppy as it is born, placing a warm bottle underneath, and bring it back to the mother when the last birth has occurred. At this time the bitch should be watched carefully for any discharge from the vulva or for any evidence of straining. If either of these occurs without results, it is advisable to send for help as early as possible, especially in the case of the smaller breeds. Many hundreds of bitches are lost through neglect at this time, and usually because it was not suspected that anything was wrong. If the discharge becomes bloody, or green, help should be obtained *at once* if no puppy is delivered. Similarly, any great delay between births is a matter for concern. The afterbirth usually follows the puppy within a few minutes, but puppies are sometimes delivered in their fœtal membranes, and in this case the latter should be gently but quickly removed. It is quite normal for the umbilical cord to remain attached to the puppy, but the bitch will normally break it by biting through it.

The mother will wash and attend to the new born puppies, and after the last is born it is a good idea to burn all the mess and to provide clean newspaper, but do not worry or frighten the bitch more than is necessary. For the care and feeding of the bitch and her puppies see the sections on Management and Feeding. Puppies, like kittens, are born with their eyes closed, but open them after about nine days—there again being considerable variation.

The phenomenon of pseudopregnancy is common in bitches, and indeed to a minor degree it is probably present in most bitches following an œstrus without conception. In some bitches, however, presumably those with strong maternal drives, the changes in the ovary may be accompanied by external signs of "phantom" or "ghost" pregnancy. These may include not only enlargement but actual functioning of the mammary glands, and the making of a "nest" by the bitch just as if her puppies were really due. The average duration of pseudopregnancy is usually given as about two months, and although variable, it is often sufficiently near to the correct time after œstrus that everyone suspects the bitch to be truly pregnant. The condition may be suppressed with the aid of modern drugs, but in some instances it is not realised that the condition is not real. In many cases only professional
advice can solve the mystery, and radiographic
examinations have often proved necessary
ascertain the truth, particularly in fat bitches
the heavier breeds. It might be well to note,
this point, that there is another condition of t
older bitch that is known as *Pyometra.* Th
condition usually reveals itself at the same ti
as the ghost pregnancy (and is sometimes a path
logical extension of it) but is accompanied
considerable disturbance of health, coupled
many instances with purulent discharge from t
vagina. A bitch which is off-colour in the wee
following pregnancy, or which develops a dischar
from the vulva (especially one which is dark
colour), may well be a pyometra subject. T
disease is most serious, and often requires surgic
intervention. As the best chance of success is
operate or otherwise deal with early, a veterina
surgeon should be consulted immediately.

DISEASES AND INJURIES OF THE DOG.

Canine Distemper and "Para-distemper
(Including so-called "Hard-pad").—It has lo
been recognised that the commonest and mo
serious disease of dogs throughout the world
canine distemper. Dogs of all ages and bree
are susceptible, and no dog is free from the ri
of infection unless it has recovered from t
disease or has acquired an immunity for oth
reasons (*see* **P8**(2). The disease is caused p
marily by a minute agent known as a filterab
virus (*see* **P7**(2). which may be of varying type
that it will attack the body in different way
Thus some strains of the virus are known
"neurotropic" because they show an affinity f
the nervous system. Sometimes a dog w
apparently recover from an attack of distemp
only to succumb later to "fits" or other nervo
manifestations due to permanent damage to t
central nervous system by the virus. Ofte
however, the virus is not fatal in itself, but w
lower the dog's resistance and permit the ent
or the activity of bacteria that may lead
pneumonia or other serious effects. These s
called "secondary invaders," as the bacteria a
termed, may prove as harmful as the origin
virus. Indeed, once these bacteria have set
work it is too late to expect the best results fro
the use of serum, and whether or not the dog w
live through will depend upon the severity of t
attack, the dog's powers of resistance, and go
nursing. It is therefore most important eith
to prevent the disease by vaccination or to
able to send for veterinary attention (and hen
for an injection of serum) *immediately* an attack
suspected. Any puppy which is listless or
its food, or which may throw a fit, or which
obviously unwell with other symptoms (*e.*
cough or diarrhœa) may well be in the early stag
of distemper, and it is *then* (not the next day) th
help should be sought. Many thousands
puppies (and older dogs) that have been inject
with serum in the early stages of the disease ha
become perfectly normal within forty-eight hou

nfectious Hepatitis or Rubarth's Disease.—
other virus disease of dogs (and foxes) is known
Rubarth's disease, after one of its discoverers,
y known as infectious hepatitis. This disease
been recognised in Sweden ever since the 1930s,
in Great Britain only since the end of the war.
e condition is extremely sudden in onset, and an
cted dog may be found dead. Many cases are,
vever, mild, and in some instances only one
two out of a large group of dogs have been
cted. The changes seen after death vary, but
findings in the liver cells are usually character-
c. Specific treatment is not yet established
in the case of the distemper-like conditions,
hough the administration of antibiotics (*see* P9)
y prevent the effects of secondary infection.
effective vaccine is now produced and often
nbined with the distemper chick embryo
cine. A dog is thereby protected against both
se diseases.

anine Hysteria (called "fright disease" or
nning fits" in the U.S.A.) is an alarming
not necessarily serious condition (in that it can
en be cured very readily) which appears to
e from a variety of exciting causes. The
cted animal rushes around wildly, often
eaming and howling, and obviously loses all
se of whereabouts or ability to recognise
ple. After a more severe attack (and there are
degrees up to a full epileptiform fit) the dog
y appear quite exhausted, but returns to
mal. Sometimes there are many attacks in
day. The dog will not wilfully attack people
ing a bout of hysteria—at least, that has
n the experience of the writer—but is very
cult to control. Apart from ensuring that
dog does itself no grievous bodily harm,
re is little that can be done until the attack
subsided. Then the animal should be kept
quiet as possible and given a tranquilliser.
Iysteria may be an hereditary taint, derived
n one or other parent. In certain circum-
nces, however, it may arise in apparently
mal animals. There are several possible
ses (including parasites), but a definite one is
bleaching agent—nitrogen trichloride or
gene "—employed for some years in the
nufacture of flour, and hence present in white
ad and certain dog biscuits. Indeed, the
r demonstration that agene could set up
teria in dogs, and subsequent scientific work,
led to the introduction of regulations that
e led to its abandonment as a bleaching
nt in favour of other methods which have
n found not to cause hysteria. There has
ady been a marked decline in the incidence of
teria due to dietary factors.

abies is a fatal disease of dogs, and is also due
" filterable virus." It is transmissible to the
nan being and to many other species, but has
unately been absent from Great Britain for
ny years. Stringent precautions are taken to
vent its entry, and dogs which are brought
Great Britain must spend a long period in
rantine. A vaccine is available and people
ng dogs to countries where rabies occurs
uld have their animals protected. Many
ntries insist on this prodceure.

onsilitis appears quite frequently in dogs, and
ns in many cases to be part of a more general-
infection. It demands expert treatment, but
ough it may persist for a long time, it usually
ls to treatment.

Nephritis.—Inflammation of the kidneys is unfortunately all too common in dogs, and in adult males in particular there is a high incidence of chronic kidney damage. One of the symptoms is a marked thirst. Sometimes this condition is a sequel to an infection known as *leptospirosis*, which calls for prompt veterinary treatment if death or permanent damage is not to follow. It is always worth while seeking professional advice for a dog that drinks excessively or has a somewhat characteristic type of bad breath. A vaccine which gives a good immunity against the two common forms of *leptospirosis* is available.

Anal Glands, which are found in the dog and in other carnivora, often give rise to trouble. Animals which "rub themselves along the ground" are not necessarily affected with "worms," but with impaction of these two little glands, which are situated one on each side of the anus. They secrete a peculiar dark-coloured, very offensive fluid, which sometimes is not discharged properly and causes the animal great discomfort. The glands in such cases should be relieved periodically. Those who do not mind this somewhat dirty task may perhaps learn how to do it themselves. Occasionally, segments of tapeworm are responsible for the impaction, but usually the trouble has nothing to do with worms. Whenever a dog pays considerable attention to his anus, this impaction should be suspected. Actual infection of the glands is also fairly common, and demands expert attention.

Diseases of the Ear, especially of the outer ear, are very common in dogs. The dog's outer ear is somewhat more complicated than is our own, and the drum is set more deeply. Hence it is easy for wax and dirt to accumulate, for various parasites to establish themselves, and for inflammatory conditions to result. The word "canker" (which has no precise scientific meaning) is sometimes applied by lay people to the more serious or chronic forms of inflammation of the outer ear canal. It is not difficult to diagnose "ear trouble," as the affected animal usually shakes its head or worries or scratches its ear and rubs it along the ground. The ears should be inspected regularly to see that there is no great accumulation of wax or dirt. Cotton-wool twisted on to the end of a match-stick or orange-stick is quite satisfactory for cleaning out the ear, providing care is taken. A dog which is continually worrying its ear, or which has ears which are obviously diseased, should not be neglected, as the sooner expert treatment is begun the more readily will the condition be cured. Even if the lining of the ear is greatly thickened through inflammatory reaction, and the lumen nearly occluded, it is still possible for a plastic operation to be performed. Many hundreds of such cases have been successfully treated in this way. A percentage of inflammatory conditions of the outer ear is associated with ear mange mites. In such an event treatment with modern antimange preparations should be carried out.

Deafness in certain white dogs (*e.g.*, in some Bull Terriers) appears to be hereditary, and is quite incurable. Old dogs often become deaf, and deafness has been produced experimentally in young puppies by feeding them on a deficient diet.

Diseases of the Eye are very common in dogs, and are often the result of injury. Except for minor discharges from the corners of their eyes (and in younger dogs especially it must be ascertained that these are not a symptom of distemper) any eye disease is sufficiently serious to merit professional advice. Boracic lotion is not suitable for the eyes of dogs. It is slightly irritant, and dogs are apt to scratch and make the eyes raw after application. Colloidal silver eye lotions and ointments are far more suitable pending the advice of a veterinary surgeon. In eye inflammation avoid sunlight and wind. For some days in the early stages of inflamed eyes, the light in the room should be subdued. Pekingese seem to be especially prone to eye disease, but the remarkably unwholesome appearance of some affected eyes in this breed is not necessarily evidence that recovery is unlikely. Steps should be taken to ensure that the dog does not inflict further injury on an already diseased eye. Cat scratches are a frequent source of inflammatory conditions of the dog's eye. Eyes must never be neglected, for the consequences are serious.

Skin Diseases are common in dogs, and may be contagious. Among the common contagious causes of skin disease are lice, mange mites and fleas. Lice and mange mites (except for demodex) are killed by modern insecticides such as benzene hexachloride (gammexane) although two applications at a 10–14 day interval are required to destroy the young stages which are within the insecticide-resistant eggs at the first dressing. The flea actually on the dog, is only one of four stages in the life cycle of the flea; the others are in the house or dog's bedding. Insecticides used for flea control should therefore be applied every week or 10 days during the summer to kill the young fleas as they hatch and infest the dog. The dog's bedding should be discarded or cleaned. The dog also suffers from other skin diseases caused by systemic disorders for which expert attention is required.

Diseases of the Teeth and Gums are very common in household dogs. A serious systemic disease, such as distemper, may leave the enamel of the teeth permanently pitted, hence "distemper teeth." More serious than this, however, is a form of pyorrhoea, which is really a disease of the gums rather than a primary disease of the teeth themselves. The margins of the gums become red and swollen, and may bleed easily. As the condition progresses the teeth may become loosened. Particles of food become lodged between the teeth or between teeth and gums, and add to the inflammation and to the smell of the breath.

This disease may, if unchecked, become very serious. In many cases extraction of one or more teeth is indicated, but unfortunately it is not always possible to do this. The condition demands expert attention.

Another common condition of dogs' teeth is the deposition around them of "tartar." This should be removed by scaling or by special use of dental forceps. Some breeders and others may themselves have learnt how to carry out these operations with the requisite skill and care, but they are not easy to the amateur, and it is essential that no harm be done to the animal's soft tissues by injudicious use of the instruments. Ordinary dog-owners are strongly advised to take their dogs to a veterinary surgeon in order to have the "tartar" removed.

Most puppies lose their first or "milk" teeth quite regularly between the ages of three and five months, but sometimes there is difficulty and the primary teeth are not shed properly. These cases should be treated by a veterinary surgeon before the permanent teeth are thrown out of their proper alignment.

One hears very much about "teething fits" in puppies, and while these occur, owners should be *very* careful to ensure that a "teething fit" is not a sign of distemper, which often starts with a fit. As puppies of this age are so susceptible to distemper, it is advisable to seek professional advice should any form of fit occur. It may save much time, money, and trouble, and even the animal's life.

Internal Parasites: "Worms."—It is probable that more nonsense has been talked and written about "worms" in dogs than about any other canine subject. According to some people, "worms" are the root of nearly all doggy evil, and so long as a dog is regularly "wormed" all will go well with him. These beliefs are frankly absurd. The real facts are very different, and are stated in as brief a fashion as possible in the following sentences. In this country dogs are
infested by a species of "roundworm" (a creatu
which is a dirty-white colour and in shape som
what resembles the common earthworm) and b
several species of "tapeworm," which are al
whitish but which are flat and are made up
many small segments joined to a little "head
which is attached to the lining of the gut. I
spite of all that is said, tapeworms as such a
rarely responsible for much harm to the do
although they can, of course, prove debilitati
and should be removed. They are a nuisance, an
attempts to remove them should be made by a
ministration of the appropriate drug. Occ
sionally, segments of worm are responsible f
impaction of the ducts of the *anal glands* (s
above).

The roundworms may be extremely serious
young puppies, in which they cause stuntin
"pot-belly," harshness of coat and dangerous
fatal illness. Fortunately, modern anti-roun
worm preparations are available for animals
this age. Once over the age of 4–8 months, do
rarely suffer serious illness from roundworm
although these may cause occasional vomiting,
even diarrhoea, and some loss of coat and bodi
condition. It is now known that puppies a
infected before birth from their mother. It
therefore desirable to keep down the inciden
of roundworms in the mother—and in do
generally—and fortunately the modern prepar
tions are—unlike some of the old-fashioned ones-
safe in use and unlikely to cause digestive distu
bances. From all that has been said abo
owners will realise the necessity of taking pr
fessional advice about young dogs which are
and any signs of "worms" in young puppies-
either in the stools or by some obvious intestin
upset or bloated appearance of the belly—shou
be acted upon. One last word about this aspe
of worms—do not assume that your adult d
has "tapeworms" unless you see some eviden
in his stools. There are so many "signs
worms" that veterinary surgeons must at tim
get a little tired of being assured that "My d
has worms" because of some trivial habit co
nected with appetite.

There is, however, another side to the study
tapeworms, and one which is not general
realised. The tapeworm which is found in t
dog represents one stage in the life-cycle. T
eggs, which are present in the ripe segment pass
by the dog, develop, not in the outside world, b
in another animal altogether. Thus one of t
commonest tapeworms in this country has
intermediate stage, as it is called, in the fle
and it is when the flea is eaten by the dog th
this intermediate stage develops further to becon
a tapeworm. Another tapeworm has an inte
mediate stage which develops in the sheep, a
a third has one which develops in the ox. The
is a fourth tapeworm which has an intermedia
stage which *may* develop in man, to set
serious diseases in certain cases. Children m
become infected through handling the dog, a
so picking up the eggs, which may then be eat
through putting the hands in the mouth. T
dogs which are most likely to be infested are tho
which have the opportunity to eat freshly kill
sheep and other food-animals. An ordina
household dog is not likely to be infested, a
people should not worry unduly in this conne
tion, provided they do not allow their dogs
stray into the wrong places. It is illegal
allow dogs to enter a slaughter-house, but u
fortunately one often sees dogs in such plac
The routine worming of dogs is justified if eviden
of infection exists, and certainly in country are
where opportunities of tapeworm re-infection m
be plentiful.

Tumours, including malignant tumours ("ca
cers") are relatively very common in the dog
probably as common as in the human subje
Space does not permit of a detailed account, b
the following examples of growths may be me
tioned: a proliferation of warts on the skin
puppies (usually disappear spontaneously);
true cancer of the tonsil in middle-aged and ol
dogs of both sexes; cancer of the mamma
glands in bitches (both incurable); fatty grow
of the vagina of bitches (amenable to operation

Space does not allow of the discussion of ot ises, but it should be pointed out that dogs are eptible to human and bovine forms of *tuber-* *is*, especially the former. In a household h contains a tubercular person, the dog ld be watched for any signs of illness, and thought entertained that he might be respon- for the further spread of the disease. For a ussion on ringworm see the appropriate head- n the section on the cat (Z12).

ccidents and Injuries.—In these days of tly moving motor transport, street accidents ogs are extremely common. Many could be ented by training the animal to walk to , by the use of a lead in busy thoroughfares, by not allowing dogs to roam the streets ccompanied—a thoroughly bad habit. Some- s the victim escapes with a scare and a few ses, and at others death is mercifully swift. he vast majority of accidents, however, a e or less serious injury is incurred, and if the nal is unable to move, the police should be fied immediately. The dog is best left quiet, it is not recommended that attempts be e to administer brandy or other supposed mulants" unless help is markedly delayed. essive hæmorrhage may in some instances prevented by common-sense application of ciples learnt in first-aid courses.

ne of the commonest accidents to dogs, cially to young dogs, is a fracture involving head of the femur, or thigh-bone. Inability ut one of the hind legs to the ground, or to bear weight on this limb, is an indication of such injury. (This injury may occur also from ng off a chair or wall.) Professional help is, ourse, required in such cases.

ts and Bruises, if not serious, may be treated ome as in the case of human beings. The scriminate use of tincture of iodine is not to ecommended, and spirit alone makes a more factory dressing in most cases. Simple ning and removal of dirt are usually sufficient, bined, perhaps, with modern antiseptic oint- ts or other preparations. The dog (and also cat) are very liable to sepsis, and it is best in cases to send for proper assistance early, or e may be grave trouble. It is probable that ature many of the flesh-eating animals end lives as victims of the sepsis following nds.

juries from cat-scratches are exceedingly mon, as are bites from other dogs. These serious, as they more readily result in septic es. The scratch or bite sometimes pene- es quite deeply, leaving a pocket which fills with pus. This pus may spread under the to form sinuses. Never neglect such places.

lusion.—There are a few concluding remarks he treatment of the diseases of the dog:—

) It is not correct that "water should be held from a sick dog." It is true that an al which is using water only to vomit, or h is drinking excessively, should have its r intake restricted, but it is wrong to deprive g altogether.

) There have been such wonderful advances e field of veterinary anæsthetics that there is adays little to fear in this connection from ations to dogs and cats. The records over past years at the Royal Veterinary College, ion and at other centres have been most en- aging, and the anæsthetic risk is now small ed.

When a dog's life is a burden to him, it is ir to keep him alive, and he should be put leep. It must be realised, however, that ing a dog to sleep is a very skilled task. made much easier if an owner will allow his rinary surgeon to administer an anæsthetic not allow the animal "to come round," and ting is also straightforward and painless if *ully* carried out. There are no "magical " of destroying human or animal life, and an r must not expect his veterinary surgeon to ble to bring about death merely by holding a to the dog's face. It is far better that the be carried out at a veterinary surgeon's own ises, where there is skilled assistance.

CATS.

Many of the general remarks in the preceding section apply equally to cats, and will not be repeated unnecessarily in the following paragraphs.

BREEDS AND VARIETIES OF CAT.

The following breeds and varieties are recognised for registration purposes by the Governing Council of the Cat Fancy:—

Long-haired Cats.

Black
White (Blue-eyed)
White (Orange-eyed)
Blue
Red Tabby
Red Self
Cream
Tortoiseshell
Tortoiseshell-and-White
Blue Cream
Brown Tabby
Chinchilla
Smoke
Silver Tabby

Short-haired Cats.

Black
White
British Blue
Cream
Tortoiseshell
Tortoiseshell-and-White
Silver Tabby
Brown Tabby
Red Tabby
Mackerel-striped Tabby
Spotted
Russian Blue
Manx
Abyssinian
Siamese (Seal-pointed)
Siamese (Blue-pointed)
Siamese (Chocolate-pointed)
Burmese

Pedigree breeding and showing are practised with a very small fraction of the total cat population of Great Britain, and the majority of these remarks will be concerned with the ordinary household cat. Nevertheless, in recent years there appears to have been a considerable increase in pedigree cat breeding. Registration—which is essential for showing and pedigree purposes—is controlled by the Governing Council of the Cat Fancy, of which the secretary (1962) is S. E. Barnes, O.B.E., 4 Elim Court Gardens, London Road, Crowborough, Sussex. Many of the breeds listed above have their own societies, which are affiliated to the Governing Council. The addresses and particulars of these and other cat societies and clubs may be had on application to the secretary of the Governing Council. The two most popular varieties of cat are the Blue Persian and the Siamese, and an exclusive show is held for each of them. In addition to these shows there are five big Championship Shows open to every variety of long- and short-haired cat, while there are classes for cats and kittens at some of the Agricultural Shows.

CHOICE OF CAT.

Although there are, as noted above, many varieties of cat, most people are content to accept an ordinary kitten, and for them the chief points to consider will be: (*a*) whether to have a long-haired or a short-haired animal, (*b*) whether to have a male or female, (*c*) whether or not to have the kitten "doctored" (*i.e.*, castrated or spayed). As a general rule, short-haired cats are probably more suitable for the average household, since their fur does not become shed so noticeably and they probably suffer less from "fur-balling." Nevertheless, many long-haired cats are so attractive that they will obviously be preferred, and there is no reason why they should not be chosen. Sex is a rather more important question, although, as may be seen in the section on management, it is possible to have both males and females "doctored." Male cats which are kept as entires are often a nuisance in that they make abominable smells in the house and spend much of their time in fighting. These characteristics are by no means invariable; but they are so common as to justify the castration of the majority of males. Siamese males in particular may be a liability. Females are generally credited with a greater attachment to the home (although they wander when "in season") and with being better mousers. The principal objection to females is that they seem to be bearing kittens almost continuously. In normal circumstances it is, of course, quite impossible to prevent cats from mating by keeping the female in confinement uring her season, a practice which is frequently adopted in the case of the dog. For one thing, most people are never aware when their female cats are in season.

Whatever animal is chosen, it is essential to pick a healthy and preferably a fairly young—but *not* too young—kitten. It is best not to accept a kitten under about eight weeks of age.

For those who wish for something a little out of the ordinary, Siamese cats make excellent and highly intelligent pets. Siamese kittens are born white, but gradually develop their even pale fawn colour, with cream on belly and chest and with "seal brown" mask, ears, legs, feet, and tail. The coat is very short, and the eyes are blue. There has long been a popular belief that Siamese cats are delicate creatures, but the present writer has seen healthy specimens, kept under ordinary household conditions, living to a mature age. It is not wise to keep a male Siamese as a household pet. The male is a fierce fighter, and is generally a worse offender in the house than the males of other breeds, and should therefore be castrated if it is to be kept as a pet.

Many people find Manx cats attractive. Instead of the normal large number of tail bones, they have but three, and hence appear almost tailless. One should beware against fraudulent amputation of the tail of ordinary cats, which are then described as "Manx."

MANAGEMENT OF THE CAT.

The cat is an independent creature, so much so that one may say that to a large extent it manages its own affairs. This, however, is not true of all cats, and every reasonable attempt should be made to provide the cat with a comfortable and friendly home. Cats are highly intelligent, and if sufficient patience is exercised they will respond to a very great degree to human attention. Kittens should not be neglected, but should be talked to and played with just as are puppies. Many cats, especially young cats, make excellent playmates for children.

In order to prevent to a large extent their nocturnal wanderings, many cats of both sexes are castrated or spayed (the popular lay expression for this is "doctored"). In the male cat the testicles are removed by an operation which is almost always safe and simple if carried out skilfully. From three to four months is a good age at which to have this done. Female cats may also be "doctored." As the female glands or ovaries lie within the body cavity, this operation is a major one, but it is nevertheless quite a straightforward, though a more expensive, procedure if conducted at the right age (about five months). Very many thousands of female cats have been so operated upon and the subsequent health of these cats has been excellent. Indeed, it has been said that a spayed female makes one of the best of all household cats.

Cats may choose to sleep in a variety of places, and will often lie on beds, chairs, mats, and other warm places. It is a sound policy to provide them with a box or basket, and to encourage them to use newspaper as a bedding. Most cats will take well to newspaper. The bed should be placed in a warm site—it is of little use putting it in a cold corner of a room and expecting the cat to lie in it.

Owing to the fact that, even in play, a cat's claws may inflict serious injury, dogs and cats do not always make the best of house companions. Nevertheless, the traditional enmity of cat and dog is often overcome, and if the two are brought up together they often make firm friends, sharing the same basket or hearth-rug and feeding together without serious consequences.

A cat normally attends to its own toilet, and everyone must be aware that a cat devotes long periods each day to cleaning and washing itself. Except in special cases, therefore, bathing is quite unnecessary, while in short-haired cats especially, grooming, too, is superfluous (this does not apply to show-cats). For some reason (and sometimes, apparently, because an owner attempts to assist in the daily grooming) an occasional cat may cease to wash or care for itself. Such an animal is a dejected sight, and should be taken to a veterinary surgeon to have its matted fur cut or combed, and
its dirt removed. Such animals (unless they co
pletely re-acquire their self-respect) must
groomed regularly if they are to be kept at all.

All household cats are accustomed to take th
own exercise, and it is advisable (except in a
special circumstances) to allow them free acc
to and from the outer world. Do not shut yo
cat in the house for a long period and then bla
it for making a mess. Cats are clean creatur
they normally dig small holes in which to defæca
or urinate, and subsequently cover the depo
with earth. If, therefore, they are for so
reason debarred temporarily or permanently fr
access to a garden, they should be provided w
a box or tray containing soil or cinders. Inde
in many types of houses it is a good plan
encourage kittens to use such a device. (Note t
corresponding remarks about puppies.)

It is generally stated that "cats never for
a blow," and for that reason it is recommend
that cats are not chastised. It may be said th
if a cat (or dog) be brought up conscientiously a
well, it should never, or very rarely, require su
punishment. An animal which has been broug
up properly seems to develop a fair sense of wh
is right and what is wrong.

For pedigree cats, or those kept in confineme
for other reasons, see the relevent remarks in t
section on breeding.

FEEDING THE CAT.

Although most cats are capable of suppleme
ing their diet by catching small rodents or bir
it is unwise to rely on this as a regular source
food. The idea that hungry cats make the b
mousers is by no means always correct. Inde
animals that are in poor condition are less lik
to be successful hunters. Moreover, while t
riddance of pests is an excellent matter from t
human point of view—and one of the reasons w
the keeping of cats is economically justified—t
"cruel" fashion in which most cats tackle th
prey is repulsive to most of us.

It is therefore necessary and desirable to prov
regular daily feeding. Kittens should rece
several meals a day, but by the time they
six months old the number of daily feeds sho
be reduced to one, or at most two. Most c
(many Siamese are exceptions) are extremely fo
of *milk*, especially if it is creamy, and the ca
love of *fish* is well known. Many *meats*, especia
rabbit meat, are relished, and a diet high
"animal protein" is indeed the aim, alwa
provided that it contains sufficient "diet
energy." It is significant that cat's milk ha
higher content of fat and sugar than cow's mi
i.e., it is a richer source of energy. Some of
proprietary bitch-milk substitutes are nearer
cat's milk in composition than is cow's milk.

Many hundreds of cats have been reared a
bred successfully in experimental laboratories
a diet consisting, in the main, of one part of
or meat and two parts of *cooked potatoes*. T
is relatively inexpensive, and may be supp
mented by milk and by some of the propriet
cat foods.

Cats are also extremely fond of liver. Some
the proprietary cat foods—the better ones
which are excellent—and vitamin tablets cont
liver, which is a rich source of the vitamin
complex.

Within reason a healthy kitten should be
to appetite, always provided good-quality fo
are available. The amount should be restric
when they are adult, however, except for pregn
and lactating cats, which are sometimes referred
as "queens" as opposed to the male "tom
An average daily allowance of solid food fo
healthy non-pregnant adult cat should be of
order of ½ oz. per 1 lb. body-weight.

Cats are fastidious eaters; they usually s
and examine carefully any strange or doub
food. At the same time they are often gree
especially with relished food to which they
accustomed, but fortunately they can, like do
vomit very readily. Here, incidentally, is
very good tip—an excellent emetic for both
and dog is a small crystal of washing-soda, gi
as a pill. People are usually amazed at the
this simple device results in a dog's or a cat's bri
ing up undesirable food.

It is important not to overfeed cats, and ost equally important to prepare all food in a n manner, and to make it as attractive as ible. Cats will greatly appreciate this care. le milk is an excellent food for kittens (see er breeding), and is relished by most adult , it must be supplemented by solid food.

ean fresh water should be provided at all s, even if the cat appears to drink it but e.

BREEDING OF CATS.

edigree animals are normally confined, and r breeding is strictly controlled. Ordinary sehold cats are at the opposite extreme, and e is little that can be done to prevent their ing. The length and scope of this article not permit of a discussion of controlled ing.

ientifically, there is as yet a good deal to n about the reproductive behaviour of the As an American physiologist has succinctly it in a description of the reproductive cycle he female cat, "no two authors agree." In thern Europe there are two main heat periods ear, in spring and early autumn, but some nals may appear in heat at any time from uary to July, and those who keep female cats nfinement describe their charges as "calling" e frequently if not mated. A cat which is season" or "on heat" is often observed to behaving in a quite characteristic fashion, ng about on the floor and making peculiar ds. The periods of heat, which commence lly at about eight months of age, may last everal days, and during this time the female make every attempt to find a mate.

estation lasts about nine weeks, as in the case e bitch, but here again there is a considerable ation. As most owners are quite unaware e time at which their cats were mated, it is ult to talk of "going overtime," but if there y evidence of trouble during pregnancy, or irth, veterinary advice should be obtained. oon as a cat is obviously pregnant, her food vance should be increased, and she should be ved plenty of milk. It is highly important to ase her food and milk ration still further the kittens are born, as lactation is a great on the mother.

ts sometimes choose strange, out-of-the-way s in which to litter, and many healthy litters born and reared out of doors. Rats are a e of danger, and will often destroy very g kittens during the mother's absence. For and other reasons it is better in town and rban areas to have the litter comfortably ed indoors. A wooden box containing news- r is ideal, provided it is kept in a fairly warm and out of the way of draughts. An average consists of three to six kittens, which are blind, but which normally open their eyes eight or nine days. There is no need to be ed if the eyes remain closed for a few days r. Kittens which are born dead should be ved and buried or burnt. If the whole is born dead, the mother's food supply d be cut down considerably, and little milk for a few days. If the mamary glands ne inflamed, they may be bathed in a cold ion of alum. The glands normally return eir former size within a short space of time ey are not milked, but if there is persistent le veterinary advice should be sought.

hile many pedigree owners wean kittens at to five weeks of age, it is strongly advised the household cat be allowed to continue to her family for a longer period, and eight s is not too long if the mother is still in good y condition. She *must*, however, be well nd be allowed plenty of milk. As in the of puppies, it is an excellent idea to provide ittens with a little solid food as from a few s of age. It is very wrong to remove a from its mother too early, and such an al is often weakly, develops an intestinal ion, and dies as a miserable bedraggled ure. Moreover, during the period following ing the mother educates her offspring in the f living, particularly ratting and mousing.

many litters are unwanted, some people get all the kittens as soon as possible after birth. ning is frequently practised, but it is not recommended as a merciful death. Indeed, a hard blow on the back of the head is more humane if given accurately. It is much better to take the kittens to a veterinary surgeon or clinic.

DISEASES AND INJURIES OF THE CAT.

The principal infectious diseases of cats are still in need of much scientific study. It is now clear, however, that there are at least two major cat plagues. Both have been given many names, and there is much confusion between them.

Feline Enteritis or Panleucopenia.—This is a highly infectious disease, due to a filterable virus. The symptoms include loss of appetite, sometimes accompanied by a rise in body temperature, followed by listlessness, usually vomiting, sometimes diarrhoea, and a marked tendency to show tenderness or pain on being handled. This tenderness or pain is due to a developing peritonitis. The poor animal may become seriously ill, with loss of water from the tissues or dehydration, prostrate and dead within 48 hours or less from the time of the first symptoms. The incubation period of the disease is believed to be from 4 to 8 days, or sometimes longer. There is a fall in the white-cell count of the blood, hence the term "panleucopenia." Some cats recover, the recovery rate in different outbreaks that have been studied ranging from 30 to 80 per cent., and recovered animals are probably immune to further attacks. Cats that are able to take a little food during the early stages of recovery have the best chance of recovery, but require careful nursing. There may be complications during the convalescent stage due to secondary bacterial infections or to vitamin deficiency, and a light nourishing diet, combined with vitamin preparations, is recommended. Fleas may transmit the disease to other cats, as may contact with infected materials. It has been shown that bedding and dirt trays from sick cats were infectious for other cats for up to 16 days. The disease is not transmissible to dogs or to human beings. There is nowadays a protective vaccine, and it is a wise precaution to have your pet vaccinated.

Feline Pneumonitis.—This disease is sometimes called "cat distemper"—as indeed is feline enteritis—but it has no connection with dog distemper, and is not transmissible to dogs or to human beings. Both mild and severe forms occur, and the incubation period varies from 5 to 8 days. The mild form may seem like a cold, and there is a weeping from the eyes and a varying degree of conjunctivitis. There is a thin, clear discharge from the nose, with a characteristic sneezing. Provided that the animals can be made to continue eating, and are kept in warm and dry but ventilated conditions, recovery may be rapid and not entail serious loss of condition. The eyes should be treated with a suitable preparation, such as silver vitellin. There may be secondary bacterial infection in cases that are neglected.

The severe form of the disease has similar, although more severe, commencing symptoms, but the nasal discharge becomes purulent and there is often profuse salivation, with much spreading of the long ropes of saliva. The cat is listless, dislikes strong light, and seems to resent being disturbed. It loses its appetite, and rapidly becomes thinner over a period of from 2 to 5 days or so. Breathing becomes laboured, and a bronchopneumonia develops. There may be a high death rate in young kittens, and pregnant females may abort. Recovery tends to be slow, and is often complicated by bacterial infection. Some of the modern antibiotics appear to be highly effective in the treatment of many cases of this disease, but they must, of course, be given under veterinary supervision.

Tuberculosis.—The cat, like the dog, can contract tuberculosis, but so far as is known only the bovine form has been known to infect it. The infections usually comes, of course, from milk, and the elimination of bovine tuberculosis from this country will stop the incidence of the disease in cats. The disease commences in the abdomen, but may spread to the lungs. There is general wasting.

Skin Diseases.—As in the case of the dog, skin disease in the cat is usually of parasitic origin, and fleas and mange mites are again the chief source of trouble in Great Britain. Cats do so much of their own toilet that the average household cat has probably a cleaner skin than its canine counterpart. When skin disease does develop, it is strongly advised that the animal be taken to a veterinary surgeon for appropriate treatment. As a rule cats greatly resent the interference which must accompany any attempt to bathe or dress an affected place, and for this reason it is usually unwise for an owner to attempt to do other than make an inspection. Very small patches of skin eruption may clear satisfactorily if the surrounding hair is clipped away with curved scissors, but generally speaking skin disease calls for professional attention. The cat flea has a similar life cycle to the dog flea (*see* Z8).

Diseases of the Ear.—The outer ear of the cat is frequently affected, and in a great many cases a form of mange mite is responsible. The animal provides evidence of the trouble by scratching and shaking its ear and generally showing its discomfort. It will not always be possible for an owner to make a thorough examination, as in many cases the cat objects, but if it is possible to look inside the ear it will be seen that there is a dirty and usually brownish mess of tissue, sometimes mixed with dried blood or pus. Not all cases are as bad as this, of course, but if a cat persistently worries its ear it should be taken to a veterinary surgeon. There are satisfactory dressings for this condition, and owners will be able to dress their cats if the latter are docile. Otherwise it is necessary to have the ears dressed by a veterinary surgeon or by one of his staff.

A cat's ear is frequently the site of a blood blister, or hæmatoma. This is usually the sequel to a blow, such as a slamming door, and shows itself as a large, tense swelling, which when opened by the surgeon proves to be an accumulation of serum usually tinged with blood. Some cases become infected at the time of injury, some after with the patient's rubbing. With the greatest surgical skill in the world one must expect a slight deformity, and the cat develops a puckered ear, much the same as the human boxer.

Disease of the Bladder.—The bladder is a common seat of disease in cats, and is frequently affected through the blocking of the natural water-passage by small sand-like calculi. Naturally, male cats are more often affected, as the terminal end of the urinary tracts is wider and more dilatable in females. The urine is unable to escape, and the bladder becomes filled with a mixture of urine and the sandy calcular matter. The condition may be diagnosed quite readily, as the cat usually collapses, or partially collapses, and one may easily feel the distended bladder through the walls of the abdomen (belly). It is necessary to send for professional help immediately, and, while no relief can be guaranteed, it is often possible to relieve the condition by judicious manipulation. Owners should not attempt to do this themselves (unless help cannot be obtained), as they may easily burst the bladder. As the animal is usually in a state of collapse when the condition is discovered, it makes a bad risk for actual operation, and relief by *skilled* pressure is usually to be recommended.

Ringworm.—There are two common kinds of ringworm in the cat (a third, which may also infect the dog, is more rare; it is the trichophyton which is usually found on cattle). The first kind is acquired from rats and mice, and is most commonly to be found at the bases of the claws, from where it may spread to the ears and face. The individual lesions are circular and yellow in colour, and consist largely of a scabby material. This kind of ringworm is known as "favus."

The second type of ringworm (microsporon) is more important, because it is more readily transmissible to human beings. Whereas this form usually sets up circular scaly lesions in the d
it often infects cats without there being mu
naked-eye evidence of its presence. Indeed,
the cat the condition is often unsuspected u
the owner himself becomes infected and consu
his doctor.

Ringworm should be treated or dealt with
a veterinary surgeon, who will also confirm
refute by special methods the presence of mic
sporon in cats.

Intestinal Parasites—" Worms."—The cat a
is subject to both roundworms and tapewor
The roundworm which parasitises cats in t
country is similar to that of the dog (althoug
different species) and is also much more harm
to the young than to the adult animal.
kittens the symptoms are a general unthriftine
staring coat, and in some cases diarrhœa and
" pot-bellied " appearance.

The commonest cat tapeworm in this count
is one which passes its intermediate stage in t
rat or mouse, or sometimes in other roden
The tapeworm, which, as mentioned under t
section on dogs, is dangerous to man, is son
times found in the cat also.

Accidents and Injuries.—Despite their sagac
and alertness in many ways, cats seem curiou
unable, in many instances, to acquire road-sen
They are dazed by a car's head-lights, while i
motorist sounds his horn they tend to stop s
in their tracks.

Injuries from traps, *e.g.*, gin-traps, are v
common, and it is probable that many thousar
of cats annually are maimed in this fashion. C
suffer injury from shooting, from stoning, a
from blows with sticks. Since they are predato
animals, they have often to pay the pena
inflicted on them by wrathful people. Needl
to say, cats which survive to return home usua
require expert treatment.

Poisoning may be included under this headi
Although there are doubtless many deliber
attempts to poison marauding cats, alleg
"poisoning" is often no more than a case
feline enteritis, and owners should not claim gli
that their cats have been poisoned until they h
expert evidence to back their judgment.

Fur-balling, as it has been termed, may
mentioned here. Cats, especially the long-ha
varieties, must often ingest hair during th
toilet, and occasionally serious trouble (a st
page of the bowels) is brought about by a mass
such hair which has collected in a part of
bowel. There is constipation, loss of conditi
and often evidence of considerable pain. S
cats should be taken to a veterinary surgeon.

Bites and scratches are even more common
the cat than they are in the dog, and subsequ
sepsis is equally likely.

FERRETS.

Description.—The ferret is probably a domes
cated form of the pole-cat (*Mustela putorius*), a
is known sometimes by that name and sometin
as *Mustela furo*. Most tame ferrets have p
eyes and yellowish-white fur, but there are dar
forms believed to have resulted from crossing
previous generations with wild pole-cats. Inde
these darker forms are popularly termed " po
cat ferrets." They are of two main kinds,
first having creamy under fur and black gu
hairs, and the second being a chocolate-bro
colour, with brown upper parts and black un
parts, and a few scattered light hairs on the fa

Ferrets are long creatures in relation to th
body weight, and when fully-grown may hav
body 14 in. long or more and a tail of 5 in. So
strains grow appreciably larger. The main
of the ferret is, of course, in rabbiting, for wh
purpose they have been employed for ma
centuries. Although they can become fierce
not accustomed to regular handling or k
treatment, and are capable of inflicting a na
bite, they may nevertheless be made into do
and highly intelligent pets. It is most importa
to win their confidence from the beginning and
accustom them to regular handling from the ti
they are young " kittens."

Accommodation.—Ferrets must have dry, clean ommodation in a room free from draughts but ll ventilated. Wood is warmer than metal, t more difficult to clean, and is best lined with rd asbestos sheeting, which is resistant to ter. The most suitable accommodation com- ses a sleeping compartment of similar pro- rtions to a small kennel, leading by a small orway or " pop-hole " to a wire-netting exer- ng run, which should be as large as possible npatible with cleanliness. It is a good idea have a means of closing the doorway so that ferret or ferrets may be confined within the eping-compartment if necessary. Wood-wool kes an excellent bedding, but if difficult to ain newspaper may be provided for the ferret lie on. The floor of the run may have a false tom or may be sprinkled with sawdust. It is perative to keep the whole of the accommoda- n clean and dry, not only to avoid smell but o to prevent the ferrets from developing a very ious necrotic infection of the feet known as oot-rot."

eeding.—Many ferrets are unfortunately not adequately. It must be appreciated that ically they are carnivorous animals, and that ir food requirements are more similar to those the dog and cat than those of rodents. In- d, many of the general remarks made about principles of feeding dogs and cats apply to rets also.

lost ferrets like bread-and-milk, and while s is an excellent article of diet, it is in itself dequate. Up to about 4 oz. of raw meat nced for younger animals) daily is an excellent is, and this may be replaced by fish. Liver, ecially raw liver, is an excellent source of many tors, and there is good reason to provide some least weekly if it can be obtained. Failing , it is advisable to add 1–2 per cent. of whole liver to the diet. Once ferrets are grown, feeding daily—at a fixed time—is sufficient. e female (jill) should have ample supplies of k just prior to the birth of her young and while is suckling them.

reeding.—In the northern hemisphere the ale ferret usually comes into œstrus (season) arly March of the year following that in which s born. If the jill does not conceive during œstrus she will have a further œstral period uly or August The desire of the jill to mate ery strong, and if not allowed to do so, some nals sometimes have been found to waste and e. The act of mating is prefaced by very orous behaviour on the part of the male (hob), anyone not appreciating the performance ht think that he was out to kill his mate! mating act itself is usually prolonged, and y take up to three hours. If left together the and jill will probably mate from two to four es during the course of a couple of days. As he cat and rabbit, ovulation or the shedding he egg from the ovary takes place as a result nating, and not spontaneously. The period estation is forty-two days, and the numbers of ng born usually varies from five to thirteen, average litter being six to eight. Pseudo- gnancy occurs if the jill is not mated, and may ome outwardly obvious as in the case of certain hes.

ales also have a seasonal rhythm, their acity to fertilise being greatest from early rch to August. Young hobs seem to be active ut a month earlier than older ones. The th of daylight or, rather, the incrementation ght from day to day, has an important bearing breeding capacity in both sexes, and by the of artificial light it has proved possible to ice either œstrus or male activity at different es of the year.

he young are hairless and blind, and weigh the average under ½ oz. at birth. Their eyes n at about four weeks, and they can then mence to eat small pieces of solid food to plement their mother's milk. They may be ned at from six to eight weeks.

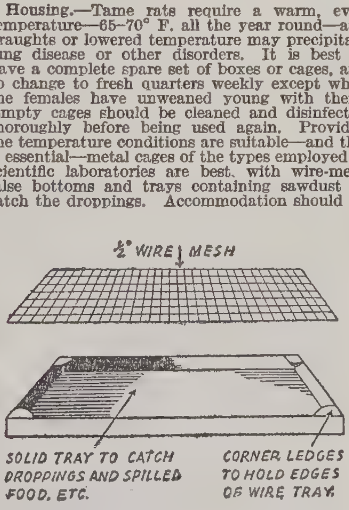
iseases.—The most serious disease of ferrets is *ne distemper*, and the variant known as " hard pad " (see under dog) is equally capable of infecting ferrets. Such infections can wipe out entire stocks, and every care should be taken to prevent their spread from dogs to ferrets—and vice versa. A veterinary surgeon should be consulted immediately when a ferret becomes ill or out of sorts. Ferrets are also susceptible to some strains of *human* influenza, and should not be tended by persons with colds or with any indications of "flu." The feeding of infected milk may give rise to *tuberculosis* (now unlikely in Britain). *Foot-rot* has already been mentioned, and must on no account be neglected. *Mange* or " scabies " of the back and tail region should be dealt with promptly, employing modern preparations. Abscesses of the neck region are often encountered, and should receive professional treatment if they do not clear up rapidly, for they may spread with dire consequences.

RATS.

Description.—Tame rats are domesticated varieties of the wild Norway or " brown " rat (*Rattus norvegicus*). Such rats are usually albinos or black-and-white, although other colours have been bred. The hooded varieties are those in which the head and foreparts are mainly black or chocolate and the remainder of the body, apart from small patches the same colours as the hood, is white. Tame rats differ materially from wild ones in disposition, and properly managed are extremely tractable. Healthy specimens accustomed to handling bite only when frightened, *e.g.*, when a sudden movement is made in front of them. Males appear to live longer than females, but three years is a good age.

" Black " rats, *i.e.*, the species (*Rattus rattus*) sometimes known as the ship or Alexandrine rat, have been bred in captivity, but tame strains are not generally available.

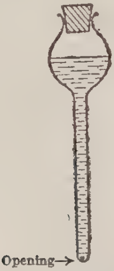
Housing.—Tame rats require a warm, even temperature—65–70° F. all the year round—and draughts or lowered temperature may precipitate lung disease or other disorders. It is best to have a complete spare set of boxes or cages, and to change to fresh quarters weekly except when the females have unweaned young with them. Empty cages should be cleaned and disinfected thoroughly before being used again. Provided the temperature conditions are suitable—and this is essential—metal cages of the types employed in scientific laboratories are best, with wire-mesh false bottoms and trays containing sawdust to catch the droppings. Accommodation should be ample, and even for a pair of pet rats the cage should measure about 30 in. × 18 in. × 18 in. If wooden boxes are employed it may be desirable to line them with hard asbestos sheeting or galvanised metal to prevent damage from gnawing.



½" WIRE MESH
SOLID TRAY TO CATCH DROPPINGS AND SPILLED FOOD, ETC.
CORNER LEDGES TO HOLD EDGES OF WIRE TRAY

Small, dark " shelters " and exercising devices, *e.g.*, wheels or ladders, are appreciated by the rats, but must be kept clean. Wood-wool makes the best bedding.

Feeding.—Rats may take a wide variety of foods, including many of our own, and there are several successful ways of feeding them, including the provision of specially formulated "rat-cubes," of the same type as that described below for mice. A good daily diet is wholemeal bread, mixed cereals (*e.g.*, oats, wheat, hempseed), with about 5 per cent. dried brewers' yeast and milk either fed separately or mixed with the rest of the food. Twice weekly each rat should be given up to ½ oz. or more of meat, liver, fish, or other "animal protein." A little fresh greenfood (even grass) is appreciated, and in winter especially some supplement containing vitamins A and D is desirable. Expectant and nursing mothers should have as much milk as they require. Never overfeed or allow uneaten food residues to remain in the cage. Fresh water (preferably in bulbs or bottles) should be available at all times. Far cleaner than open dishes are the special but simple type of water bulbs suspended on or in front of the cage or box so that the rat can drink from the rounded end of the spout. A simple substitute is a medicine "flat" bottle—or even a ½- or ⅓-pint milk-type bottle. This should be fitted with a cork—or, better, a rubber bung—pierced for a piece of bent glass tubing. Provided that the free end of the glass tubing is not sharp, and is chosen so that the aperture is considerably smaller than that of the tube itself, the water will not run out unless sucked out by the rat. The spout should, of course, be within easy access of the rat, which will soon learn to drink from it.



WATER BULB SUITABLE FOR USE WITH PET RODENTS

Breeding.—Rats can breed at quite a young age (usually being capable of mating when fifty to sixty days old), but it is better to separate the sexes within a fortnight or so of weaning (weaning being usually at twenty-one days of age) and to mate at about 100 to 120 days of age onwards. the female rat has an œstrous cycle lasting just over four days. One male (buck) may be mated to one female (doe)—this is probably best in the case of pet rats—or with two or three females if preferred, but it is unwise to keep more than one adult male in the presence of females. The gestation period is twenty-one to twenty-two days or occasionally a few days longer. The number born varies considerably, but often it is best to try to rear only six to eight young. The young have their ears open at 2½ to 3½ days, cut their incisor teeth at eight to ten days, can find their way to their mother at about the same time, open their eyes at fourteen to seventeen days, and may leave the nest at twenty-one days. In the case of pet rats it is probably best to leave the young with the mother for up to a week or so longer. Breeding can occur all the year round, but takes place less readily in winter.

Handling.—Rats should not be "tailed," or the skin may slough off. Regular handling after weaning is excellent and promotes docility. The weight of the body should be supported.

Diseases.—On the whole rats are much less liable to disease than mice, provided temperature conditions are suitable. The commonest infection is *broncho-pneumonia*, often precipitated through draughts or cold. *Mange* (especially of the ea
and infestation with *lice* may occur, and shoul
be dealt with promptly by means of moder
insecticides. Avoid contact with wild rodents,
the use of food or bedding that may have bee
contaminated by wild rats and mice.

MICE.

Description.—Tame mice are descended fro
the common house mouse (*Mus musculus*), and
is believed that mice have been domesticated f
over 3,000 years. Apart from albino or "whit
mice," there are many varieties that have bee
bred by the extensive "mouse fancy," and the
is a wide range of coat colour and also differe
types of coat, *e.g.*, long-haired, short-haired, a
rex. "Waltzing mice" have an abnormality
that part of the inner ear concerned with balanc
Mice may live up to thirty months, and in exce
tional cases attain the age of three years
more.

Housing.—Although strains vary, most tam
mice require a warm even temperature and th
same general remarks concerning temperatu
range, bedding, and wooden or metal cages app
as in the case of rats. If a solid floor is use
this should be covered with clean sawdust.
is a good plan to change to a clean cage regular
except when the female (doe) is nursing her youn
If the cage is large (as in the case of pet mice
should be, with a floor space of say 24 in.
12 in. × 12 in. for a group of mice), inner nes
boxes should be provided—one for each doe
breeding is taking place, although two does w
often share the same nest-box. (In changing
fresh cages the nest-box, with mother and youn
inside, may, of course, be moved over.) A "tw
storey" cage, with a ladder or "staircase"
the upper part, is an attractive variation, althou
difficult to keep clean. Mice should be kept w
out of reach of wild rodents, from which they m
all too readily contract disease.

Feeding.—Mice have not quite such a wi
dietary range as rats, but there are several diffe
ent ways of feeding them, including the provisi
of special "mouse cubes." These mouse cub
are of varying composition. One of the mo
successful, devised by workers in the Medic
Research Council's laboratories, is known
"Diet 41," and is made up of the following par
by weight: wholemeal flour, 45; Sussex groun
oats, 40; fish meal, 8; dried yeast, 1; dri
skimmed milk, 3; cod-liver oil, 1; and comm
salt, 1. Diet 41 has also been employed for ra
and monkeys, although for the latter particular
it requires supplementing. It is perhaps wor
emphasising that cod-liver oil must not be f
in excess (½% of the diet is quite sufficient, a
should not be exceeded), or it may preve
breeding and possibly have other harmful effect
Cubed diets are best fed from a wire bask
through which the mice enjoy gnawing a
eventually pulling out the pieces. Wholeme
bread is excellent if not allowed to become sta
but it should not form the sole article of diet, a
it is a good idea to feed it alternately with a gra
mixture (made up of rolled oats, wheat and oth
cereal grains, or mixed bird seed). Up to abo
5 per cent. dried brewers' yeast is excellent, a
so is fresh or dried milk, especially for mothe
that are carrying or nursing young. Cheese
relished, but may smell if not fed careful
Mice sometimes like an occasional pinch of marm
lade, and it is a good idea to provide lettuce
other greenfood every week or so. There shou
be a constant supply of fresh water, preferab
from bulbs or bottles as described for rats.

Breeding.—Young mice may be weaned
twenty-one days, although it is usually preferab
to leave them with their mother for a furth
week. The age at which mice are capable
mating varies considerably from one strain
individual to another, and while the average
six to eight weeks, it may be much younge
It is therefore desirable to separate the mal
from the females at or shortly after weanin

ce may be mated up at two to three months of e, and the best arrangements are one male ıck) to one or two females. A pair of mice or " bigynous trio " makes a successful combina- n. The œstrus cycle is similar to that of the , but its length appears to vary with coat our, being longest in the brown mice and ortest in blacks and albinos. The gestation riod is usually from eighteen to twenty days, t may be prolonged if the female was still ckling her previous litter when she conceived. ere may be up to twelve or more young in a er, but the average litter size is from five to ven. The second litter is usually the largest, d subsequent litters tend to decrease in num- rs, so that the sixth is usually smaller than the st. Breeding may take place all the year round, hough, as with rats, fertility is higher during e summer months.

Handling.—Any rapid or rough movement may ghten mice and cause them to bite through fear. ce should be lifted by the tail—not too near the —and may be held in the palm of the hand, ere they may be suitably restrained by keeping e tail between two fingers.

Diseases.—Mice are unfortunately prone to ny diseases, although the risks will be much ver if they are kept in suitable surroundings, eat care is taken to avoid infection, scrupulous anliness is observed, and the standard of feed- is good. One common source of infection is e presence of the excreta of wild rodents on lding or foodstuffs. A common disease is that netimes called "*mouse typhoid*," caused by ganisms of the Salmonella group. Although ne mice recover, they may remain carriers of ection, and once this disease is diagnosed it is t to destroy the affected mice and those in ntact with them, and not to employ any of the ges or utensils for fresh mice without adequate rilisation. There are other septicæmia diseases mice, and also virus diseases, including certain pes of *pneumonia* and a condition known as *ectious ectromelia*. The accurate diagnosis of ese calls for expert opinion and often for special cteriological or other examinations. The use-owner should, however, be able to recognise ns of ill-health or departure from normal, one the commonest being loss of appetite. In ng mice the coat should be smooth and glossy. mice get older there may be loss of pigmenta- n (in coloured mice) or even loss of fur. A sick use usually sits hunched up and has a ruffled t, while the eyes may be partially closed or ve some discharge. A healthy mouse will ally catch on to suitable objects when held by tail and is capable of pulling quite hard, ereas the pull of a sick mouse is much weaker. one or more mice die it is best to destroy at e any cage-mates that appear seedy. As in case of rats, external parasites should be dealt h promptly with the aid of modern insecticidal parations.

GOLDEN HAMSTERS.

Description.—There are many species of ham- rs in the world, and more than one kind can v be bred in captivity. The one referred to, vever, is the Golden Hamster (*Mesocricetus atus*), a delightful little creature of which a full- wn female (females are larger than males) ely exceeds 7 in. in length. This history of the nestication of the golden hamster is quite narkable, for prior to 1930 only museum speci- ns were known. In that year a mother and twelve young were dug up in a field near ppo and were taken to the Hebrew University, usalem, and from that one family have been d the hundreds of thousands of golden hamsters v employed as pets or as laboratory animals in ny parts of the world. The species has taken l to captivity and, although capable of inflict- a nasty little bite if frightened or handled ghly, becomes docile and friendly when pro- ly cared for. Characteristic features are the , smooth fur, the large black eyes, the " cheek pouches " in which food is stored and which may become enormously distended after a meal, the short, stumpy tail, and the extremely loose skin, inside which the hamster can turn round to a considerable degree.

Housing.—The same remarks about accommodation, environmental temperature, freedom from draughts, fittings, and other general considerations (including cleanliness) apply as in the case of rats and mice. For breeding purposes a dark inner chamber or nest-box is desirable. Several hamsters may be kept together, but the introduction of a stranger (or even the re-introduction of a former cage-mate that has been removed for some time) may lead to fighting.

Feeding.—Satisfactory diets include the following: (1) rat cubes (*e.g.*, " Diet 41 "), carrots, greenfood, and milk; (2) cereal grains and/or wholemeal bread, carrots, greenfood, and milk; (3) steamed Rangoon beans, wheat, maize meal bread, a little Marmite, and milk. Care must be taken not to allow storage of excess food, which will deteriorate and cause a smell. Grass is a suitable source of greenfood during its growing season. Apples and other fruits are often relished. Water, preferably in bulbs or bottles as described for rats, should always be available.

Breeding.—Golden Hamsters attain puberty at from ten to fifteen weeks of age, or even younger, males being usually earlier. Generally speaking, it is best to defer breeding until after fifteen weeks of age. There is an œstrus cycle of about four days, and the gestation period is very short, averaging sixteen days, although sometimes up to nineteen days. Mating not followed by conception results in phantom or pseudopregnancy. Litter size varies from one to fifteen, but the average is six to seven. Not many females have more than four litters and although both sexes may live up to two years, breeding by the female is rare after nine months. The young are naked and blind at birth. Hair first appears at five days, and covers the whole body at eight days. The eyes open at about eleven days, and soon after this the young begin to take food for themselves and may be weaned at three to four weeks. Care must be taken that the female does not injure the male, and for safety's sake it is probably better to keep only one female and one male together and to remove the male before the young are born.

Handling.—Gentleness is essential, and sudden movements should be avoided. The tail is much too short to use, and the easiest way is to lift them by the loose skin over the back and shoulders. As already noted, they can twist easily within their skins, unless a substantial amount is taken in the hand. After picking up they may be allowed to sit on the palm of the hand.

Diseases.—Several diseases of hamsters are now known, and, like most rodents, they are susceptible to *Salmonellosis* (see notes under " mouse typhoid " and " paratyphoid " in guinea-pigs). One of the most prevalent conditions is *ear mange*, in severe cases of which the condition spreads from the ears to other parts of the body. Modern anti-mange preparations are highly effective.

CAVIES (GUINEA-PIGS).

Description.—Cavies or guinea-pigs (*Cavia porcellus*) are rodents, and are descended from one or more of the several kinds of wild cavy found in South America. They are believed to have been domesticated by the Incas long before Europeans " discovered " that part of the world. They make excellent pets, but are easily frightened, and should be treated gently and quietly. They usually behave quietly, although there may be fighting between adult males (" boars "), while the arrival of food—or the entry of a person into a room, which fact is obviously connected with feeding-time—usually sets up a chorus of chirruping squeaks. There is to-day a considerable cavy "fancy" in Great Britain and other countries, and many varieties are recognised, including rough-coated and smooth-coated types. Among recognised colours are the agouti (banded hairs), brindle, cinnamon, tortoiseshell (tricoloured), and Himalayan (white with attractive black points). The long-haired Peruvian and rosette-haired Abyssinian breeds are popular. Guinea-pigs may live up to two to three years. There is a small tail (composed of from five to seven caudal vertebræ), but usually this is so short that it does not project outside the body. There are four toes on each of the fore-feet and three on each hind foot. An adult guinea-pig may measure up to 10 in. or more in length, and sometimes its weight is well over 2 lb.

Housing.—Guinea-pigs may be kept outside or inside. If outside conditions are favoured, great care must be taken to protect them from dogs, cats, and rats. The last-named may be a danger also in conveying disease. The run should be in a sheltered position away from wind and direct summer sunlight. Tent-shaped waterproof shelters, with wooden floors covered by cleaning trays, have been found satisfactory. Another method is to keep them in hutches of the same type employed for rabbits and when conditions are suitable to let them out into a temporary run on the lawn surrounded by ½ in.-mesh wire-netting that is at least 12 in. high. (N.B. This will keep dogs or cats out.) Guinea-pigs will crop the grass and help to keep the lawn smooth. Great care should be taken not to allow the ground or floor to become so contaminated by guinea-pig excreta that it conveys disease from one animal to another.

If indoor methods are selected, an even, preferably warm temperature is desirable, and there should be freedom from draughts. Guinea-pigs have been found to thrive best at about 65° F. with a humidity range of 45–55 per cent. Provided warm conditions are available, metal cages are easier to keep clean than wooden ones, while a false bottom of wire mesh, above the cleaning tray, is helpful. Wood-wool is again the best bedding. Cages must not be too small, and a pair of pet guinea-pigs should have about 14 sq. ft. of floor space. It is a sound principle, as with rats and mice, to change frequently to a clean cage, the used one being cleaned and disinfected thoroughly before being used again.

Feeding.—Guinea-pigs, like human beings, apes, and monkeys, require a source of vitamin C (ascorbic acid). Normally they obtain this from greenfood, but in winter especially they may not secure enough in this way. The daily requirement of an adult guinea-pig is about 2 milligrammes, and supplies can be obtained from a chemist's shop.

There are many different methods of feeding guinea-pigs. Among cubed or pelleted diets is that known as "Diet 18," which is employed also for rabbits. It contains the following parts by weight: wheat feed, 15; grass meal, 30; decorticated groundnut meal, 15; linseed cake, 10; barley meal, 20; common salt, 1; and chalk, 1. This is fed together with fresh greenfood to supply vitamin C. For feeding without the use of compressed diets a good plan is to provide a daily "concentrate ration" of about 1 oz. per head of a mixture of 2 parts bran and 1 part crushed oats, and to feed in addition ample amounts of cabbage, lettuce or other greenfood, meadow hay of good quality, grass, and raw vegetables. Although guinea-pigs normally derive moisture from fresh greenfood, and may appear to take little or no water for long periods, it is a mistake not to provide a fresh supply, preferably from water bulbs, or from inverted bottles fitted with a stopper and drinking-spout. A little dried brewers' yeast makes an excellent addition to the diet, while for females ("sows") when pregnant or lactating, milk is excellent. Dead foliage should be removed from greenfood, and soil and dirt cleaned off. Frosted greenfood should be soaked in warm water before it is given to guinea-pigs. Unfortunately, hay may be contaminated by wild rodents, but it forms an excellent article of diet. Never allow food resi-dues to remain in the cage.

Breeding.—The lactation period of the guinea-pig is a short one. The gestation period averages sixty-three to seventy-five days, although varia-tions of fifty-eight to seventy-two days are known and the young are born in an advanced state with their eyes already open. They can run freely with their mother shortly after birth. They are able to nibble a little food as early as the second day, and by the time they are two to three weeks old they are completely independent and are neglected by their mother. A sow will often mate again the day the young are born, or shortly after, so that a rapid succession of litters often occurs.

Guinea-pigs are capable of mating from about fifty-five days of age, or even younger in certain circumstances, which include the provision of a high plane of nutrition. The œstrous cycle averages fifteen to seventeen days, although it may vary from thirteen to twenty-five days. The actual period during which mating may occur usually lasts only from about six to eleven hours. One boar may run with as many as twenty sows if so desired, but in the case of pets it is much more interesting to run a boar with only one sow in which case she need not usually be removed to a separate cage before the young are born. The young guinea-pigs should be separated from the older ones shortly after weaning, and the sexes separated at four to five weeks of age if they are not to breed prematurely. It is better to wait until the animals are approaching six months of age or so before they are mated, for they do not become fully grown and "filled out" until they are between six and nine months.

Handling.—Guinea-pigs are timid creatures and should be handled gently. They are best picked up with both hands. If a guinea-pig is to be held in order to examine it for any purpose a good method is to place one hand over the animal's shoulders, with the fingers and thumb around its neck, and to extend its hind limbs with the other hand.

Diseases.—The most important infectious disease of guinea-pigs is, like "mouse typhoid," caused by organisms of the Salmonella group, and it may be contracted from wild rodents or from food or bedding contaminated by them. In guinea-pigs the disease is known usually as "*paratyphoid*" (or sometimes as "*salmonellosis*") and it may take an acute form, causing death within a few days, or a more chronic form in which many animals recover to become symptomless carriers of disease. Outwardly healthy, they may infect susceptible guinea-pigs with which they are placed. Cold or other environmental variations, and faulty feeding, can help to set off an outbreak, for there are few stocks in which the organisms are not lurking in some "latent carriers." *Coccidiosis* is common, but is a much less serious threat than in the case of rabbits. It has been set up in infected stocks by feeding inadequate diets, and provided that nutrition and hygiene are adequate there is rarely serious trouble from this disease. *Infections of the respiratory tract* may occur, but are uncommon except when there is overcrowding, high humidity or damp bedding. Sometimes organisms of the Pneumococcus group cause not only disease of the respiratory tract but also a generalised infection of the serous membranes of the body. When this disease occurs it may produce death without much warning. It is possible that the infection sometimes comes from human beings. The disease known as *pseudotuberculosis*, and described under rabbits, occurs in guinea-pigs also. Again environmental conditions and faulty feeding may predispose towards active infection.

With good fortune and sound management trouble from these serious infections may never occur. *External parasites* should be dealt with promptly by insecticides. Sometimes *non-parasitic skin disorders* occur when the diet is faulty, *e.g.*, too dry or lacking in sufficient fresh greenfood of good quality.

RABBITS.

escription.—Domesticated varieties of the
l European rabbit (*Oryctolagus cuniculus*) are
kept in many countries. The wild rabbit
elieved to have been introduced into Great
tain in the 12th cent. Tame rabbits have been
d for centuries, and the breeds and strains
duced differ appreciably in size, colour, and
its from the common wild form. Some breeds
e been specially bred for table purposes, while
ers (*e.g.*, the Angora, Sitka, and Argente de
mpagne) have been developed for their fur.
ddition, many varieties are produced for show
poses by the extensive rabbit "fancy." The
ll hardy Dutch rabbit (usually black and white)
ne of the kinds suitable for beginners. Among
l-known categories are the English, Japanese,
nalayan, Belgian Hare (really a rabbit),
mish Giant, Beveren, Blue Imperial, Polish,
vana, Lop, Half-Lop, Chinchilla, and New
land White. The Copenhagen rabbit appears
be identical with the New Zealand White.
smaller breeds weigh only 4–6 lb. when fully
wn, whereas some specimens of some of the
t breeds attain a weight of 20 lb. or more.
abbits and hares were formerly classified with
rodents, but are now placed in a separate
ler of mammals, known as the Lagomorphs.
ng rabbits (in contrast to leverets or young
es) are blind and helpless for some time after
h. Tame specimens may live for 4–5 years,
individuals have lived for up to 13 years.

ousing.—Since rabbits are kept for commercial
poses, various systems have been devised, inclu-
the use of movable ark-huts, with covered
s, that can be moved regularly to fresh ground.
ept indoors rabbits do not need special heating,
freedom from draughts, damp, excessive cold,
access by wild rodents is most desirable. A
ge is regarded as an unsuitable place, owing
he susceptibility of rabbits to exhaust or engine
es. One of the great difficulties of rabbit-
ping is coccidiosis, which is a serious disease in
its and hares. (European hares could never be
successfully in captivity until means of over-
ing coccidiosis were discovered.) With young
its especially (*i.e.*, those that have left the nest
are able to run about freely) it is a sound prin-
e to move them to a clean floor or fresh ground
y two days, so as to "break" the life-cycle
he coccidial parasite. One way of doing this
have "back-to-back" cages or hutches, from
to the other of which the rabbits may be
sferred easily. The empty cage or hutch
then be cleaned and disinfected thoroughly
allowed to dry out before the rabbits are
rned to it. Wood-wool makes a suitable
ding material, although the female (doe) will
k her own fur to line the nest when her litter
ue to be born. Wire-mesh floors with a tray
eath are convenient, but if solid floors are
these should be sprinkled with fresh sawdust
y or every other day. Provided the standard
ygiene can be maintained, cages or hutches
their runs should be large. The absolute
imum is "1 sq. ft. of floor space for each 1 lb.
ht of adult rabbit," *i.e.*, if there are two
its totalling 12 lb. in weight there must be at
12 sq. ft. of floor space. If cages or hutches
stacked one on top of the other the lowest
ld be well clear of the ground, and if there is
one hutch this, for convenience and safety
wild rodents, should be 2–3 ft. off the floor.

eeding.—The wild rabbit grazes at dusk and
n, and it is preferable to feed tame rabbits
e daily, while pregnant or lactating does and
g rabbits benefit from three meals a day. As
he case of guinea-pigs, the ration may be
ght of as consisting of two parts, a concentrate
ion and a portion consisting of greenfood and
succulent material. The concentrate por-
consists usually of a mixture of cereal grains
f some other form of mash. Successful
es, of which there are many, include: (1) a
ure of 4 parts cereal grains and 1 part dairy
; (2) equal parts of bran, weatings, flaked
e—or barley meal—and fish meal. This second is useful for breeding. If materials for the mash are in short supply they may in part be replaced by cooked potatoes. An average daily food allowance for a resting (non-breeding) adult of medium size would be: greenfood (grass, clover, weeds, lettuce, etc.) and/or roots, 12–16 oz.; hay (good quality), 2–3 oz.; and concentrates (cereal grain or meal mash), 2 oz. If cooked potatoes are used they should be fed at the rate of 4 parts to each 1 part of cereal that they replace. For a doe nursing her litter a suitable diet would comprise: greenfood to appetite, hay (good quality and preferably containing clover or other legume), 2–4 oz.; concentrates (preferably with fish meal or some other suitable source of "animal protein"), 4–6 oz.; and common salt at the level of up to 1 per cent. of the ration. A mineral mixture is preferable to salt alone. Excessive greenfood, especially in the form of cabbage and other Brassica plants, may cause polyuria, *i.e.*, the passage of excessive quantities of urine. No matter how much fresh greenfood rabbits may have available, a supply of fresh water should always be provided. The daily water requirement of the rabbit is quite high, and certain bad habits such as urine drinking or even cannibalism may result from an inadequate intake of water. Pots that cannot be overturned or, preferably, water bulbs or bottles as described for guinea-pigs, are the most suitable means of providing water.

"Diet 18," described under guinea-pigs, is one of several types of compressed diet successfully employed for rabbits. Fresh greenfood is preferably fed in addition, while the water requirement with diets of this kind is considerable.

Breeding.—The age of puberty varies with the breed, and also with the time of year at which the individual rabbit was born. Rabbits born in spring are usually capable of breeding at a younger age than those born in the autumn. In Great Britain the wild rabbit has a fairly sharply defined main breeding season, lasting from January to June, but some degree of "out-of-season" breeding may take place at almost all other times. Tame rabbits may not breed freely during the winter months, especially if environmental conditions are cold. Mating may take place as early as four months of age, and although this does not often result in pregnancy, it is accompanied by competition and fighting between individuals of the same sex. Males (bucks) and females should therefore be separated at weaning or at least before they are four months old. Fertile matings may occur at from about 5½ months of age onwards, but it is wise to defer breeding until later—say seven to eight months for most breeds. The female does not ovulate or shed her eggs from the ovary spontaneously as do most domestic mammals, but, like the cat and ferret, does so in response to the act of mating or some other strong stimulus. Even playing between two does may precipitate ovulation, in which case a so-called "phantom pregnancy" (pseudopregnancy) may result, the doe that has ovulated appearing pregnant and even developing lactating mammary glands. There is not therefore an obvious regularly recurring œstrus cycle as in the domestic rat, mouse, and guinea-pig, and in summer at least the doe may be ready to mate at almost any time. Observation suggests, however, that there are fluctuations in the desire to mate. The act of mating in rabbits sometimes causes alarm that all is not well to those that have not hitherto witnessed it, for the buck usually emits a peculiar cry and loses his balance to fall over sideways. It is usually best to separate the buck from the doe before the young are born. The gestation period is usually thirty to thirty-two days. In wild rabbits a high percentage of embryos die and are "resorbed," and are therefore never born. In some populations it appears that about two-thirds of all rabbits conceived (including about 60 per cent. of total litters) are lost before birth in this way. Losses from this cause are probably much less common in domesticated rabbits, especially when the standards of feeding and management are high. Litter size is variable, and depends in part on the breed or strain. In some strains mean litter sizes up to eight or nine have been obtained, but a mean of four or so is more common. Does that do not prepare the nest or rear their young properly should not be selected for further breeding. The doe with her new-born litter should not be disturbed unduly, or she may desert her young, which are blind and helpless at birth and are entirely dependent on her for at least three weeks, after which they begin to nibble food to supplement the milk that they receive from her. The eyes open at about fourteen days. Weaning should be carried out at between six and eight weeks of age, by which time the young should be able to fend for themselves completely.

Handling.—Rabbits should never be lifted by the ears alone. One good way of lifting them is to grip the ears firmly but gently with one hand and to place the other hand under the rump to take the weight of the rabbit's body. Alternatively, one hand may be placed flat under the rabbit's belly, but this requires more care, and may be a risky procedure with pregnant does. Another convenient way to handle rabbits, especially young ones, is to lift them by the loose skin over the shoulders. Rabbits can inflict quite nasty scratches with the nails of the hind feet. It is incidentally a good plan to examine the nails of all four feet and to trim them if they are too long. A stout pair of scissors, or preferably a pair of clippers, is used, and care should be taken not to cut back as far as the "quick," *i.e.*, the bluish portion at the base of the nail that contains blood vessels and will bleed freely if damaged.

Diseases.—As already indicated, *coccidiosis* is a highly important disease of young rabbits. It may be either of the "hepatic type," affecting principally the liver, or the "intestinal type," affecting principally the gut. Even in the case of the hepatic type, however, the coccidial parasites are picked up by mouth and after penetrating the intestinal walls make their way via the blood-stream to the liver. Hygienic measures are the best means of preventing the disease (see under **Housing**), but should it break out, prompt treatment with certain sulphonamides or other anti-coccidial drugs may prove effective. In certain rabbitries in which coccidiosis is a constant problem, protection has been obtained by feeding a dilute solution of one of the soluble sulphonamides in place of drinking-water. There are certain types of digestive disturbance that may resemble coccidiosis, and one of these, the cause of which has not yet been established with certainty, is known as *mucoid enteritis*. Some such cases are probably variations of "*bloat*" ("the blows") a condition the cause of which is again not fully established, although there may in fact be several factors. A rabbit may, of course, "blow" after eating fermentative food, but cases of "bloat" can occur independently of this, and some may be due to a virus. "*Snuffles*" is characterised by a nasal discharge, and is not always associated with the same organism. In its milder forms it is not a severe disease, but with the more chronic forms the nasal discharge becomes marked and gives rise to a typical snuffling noise. Severe chronic cases become progressively worse and die of a terminal pneumonia. There is also a severe acute form, in which the rabbit dies so rapidly that the condition is sometimes not recognised. Acute cases that are treated in time with certain sulphonamides may respond well, but chronic snufflers are difficult to treat and go on spreading the infection, and hence are better destroyed. Correct environmental conditions are a great help in preventing this disease. A chronic type of infection is known as *pseudotuberculosis*, which is usually acquired from eating material contaminated by wild rodents or by other infected rabbits. It is caused by quite a different organism from that of true tuberculosis, which is much rarer in rabbits. Clinical cases should be killed, and prevention lies in hygienic measures. Infected wounds or skin abscesses may lead to a disease caused by the "necrosis bacillus" (*Fusiformis necrophorus*) and known sometimes as *necrobacillosis* It is usually characterised by subcutaneous swellings distributed irregularly over the head and body. Although in the early stages the affected rabbit may remain in apparently good health, the spread of the disease
insidious and usually fatal, and in most instanc
it is kinder and safer to destroy a case before
progresses too far. There are unfortunate
several other infectious conditions occurring
rabbits, but all call for expert help in diagno
and treatment. Generally speaking, it is a b
policy not to cull an ailing rabbit immediatel
and one that is ill should certainly be isolated
once and not fed or tended before the pers
looking after it touches the healthy rabbits.

Among non-infectious conditions *pregnan*
toxœmia is not uncommon in does during the ve
late pregnancy, and usually proves fatal with
two to three days. It is a "metabolic d
order," *i.e.*, it is associated with some function
derangement of the endocrine or ductless glan
or with the inability to control properly t
utilisation of its food. Faulty feeding is probab
a contributory cause. Diseases of the *heart a*
blood may arise occasionally, and can be agg
vated by faulty feeding.

Among external parasites, *ringworm* is n
common, but may be acquired from roden
Affected rabbits that are to be treated must
isolated. *Ear mange* (known usually as *e*
canker) is common, and may be treated by str
attention to hygiene, with thorough disinfecti
of the hut or cage, and by dressing with a mode
anti-mange preparation. *Body mange* is much le
common but far more difficult to treat.

Among internal parasites, so-called "*bladd*
worms," *i.e.*, the larval stages of two dog tap
worms (*Taenia pisiformis* and *Taenia serialis*) a
quite common, although rarely fatal. The fee
ing of grass or other greenstuff to which do
have had access should be avoided, as well as t
contamination of the drinking-water with d
fæces.

Domestic rabbits are susceptible to myxom
tosis, and it is a wise precaution to have the
vaccinated. The vaccine is inexpensive, and ma
be obtained through veterinary surgeons a
pharmacists.

HEDGEHOGS.

Description.—The European hedgehog (*Eri*
aceus europaceus), found throughout Great Britai
belongs to the Order Insectivora, of which mo
and shrews are also members. Its diet is, ho
ever, by no means restricted to insects, althou
in nature a considerable portion is probab
made up of small invertebrates. There is a go
deal of prejudice against them as pets, owing
the fact that freshly caught specimens are usual
infested with fleas or other external parasite
The spines of the hedgehog, being well-space
make the presence of external parasites mo
obvious than is the case in animals with a coat
close fur. The hedgehog's spines form its defen
and its capacity to roll up into a prickly ball
the threat of danger is well known. This defen
reaction is unfortunately of no avail to it wh
the danger is an oncoming car or lorry, a
thousands of hedgehogs die every years as a res
of being killed by vehicles on the roads. Ma
other species of mammals wander on to the roa
but most attempt to flee when they sense t
approach of a vehicle. The capacity to roll
is not secure defence even against animal enemi
There are some foxes, dogs, and cats that ha
learned to "uncurl" a hedgehog, and subsequently eat it.

Provided that care is taken, a hedgehog mak
an excellent pet, especially if given a suitab
enclosure in the garden. For a variable ti
during winter hedgehogs hibernate, and duri
this time they must not be disturbed. Shou
they emerge at any time however, food must
provided. Some specimens have lived for f
years or more in captivity.

Accommodation.—The most satisfactory way
maintain a pet hedgehog is to provide it with
large "run" in part of the garden. If wi
netting is employed it should be sunk under t
ground to a depth of several inches, or the hedg
hog will burrow underneath and escape. T
top of the run must be wired in, or alternative

ere must be a "baffle board" or wire-frame (at
st 9 in. wide) near the tope of the sides to
event escape that way, for hedgehogs can scale
re-netting—and some other types of fence—
th ease. There should be a warm, dry box for
elter, containing wood-wool or other bedding
terial. A simple but suitable shelter may be
de out of a soap-box, preferably lined with
pestos sheeting or some other material imper-
ous to water. A shallow sunken bath in the
closure may be of interest, for hedgehogs take
ll to water, but the edges should be such that
e hedgehog can get out easily.

If it is decided to keep a hedgehog indoors, then
e best accommodation is probably similar to
at described for ferrets.

Feeding.—The simplest diet consists of milk,
ne bread, and minced lean meat. Cooked meat
preferred to raw, but raw liver should be given
casionally. Another satisfactory diet comprises
eat offals, "root" vegetables (*e.g.*, carrot,
tato, and swede), and wheaten wholemeal
cuit, steamed together until cooked, and then
xed and minced with a small proportion of raw
er. A small quantity (say 1–2 per cent.) of
neral mixture is also desirable, and milk should
given freely. Although hedgehogs appear to
nk but little water, a fresh supply should always
provided.

Breeding.—During the breeding season marked
anges occur in both males and females, and the
uctures associated with reproduction increase
ormously in size from about March onwards.
e female is capable of having two litters a year,
e first in May or June and the second in August
September. The period of gestation has not
en determined exactly, but is believed to be
rty-five days, possibly with variations of up to
ll over forty days. During the breeding season
e males are very pugnacious towards each other
females are with them, and may do each other
nsiderable damage. (The mixing of strange
dgehogs is often a difficult procedure anyway,
they often fight and inflict nasty bites on one
other's feet.)

The litter size is usually four to six, and the
ung, which have "soft" spines, are suckled
their mother for nearly six weeks. The young
n partake of some solid food at about three
eks, and there is some evidence that if left with
eir mother for longer than six weeks she may
mpete unfairly with them for food!

Diseases.—Hedgehogs in captivity are suscep-
le to *respiratory infections*, and can sometimes
tract certain strains of *human influenza*.
ey are susceptible also to *Salmonellosis* (see
der mice and guinea-pigs). Fleas and other
ernal parasites have been mentioned; these
en disappear spontaneously as the hedgehog
gins to thrive in captivity, but if not they should
dealt with by modern methods. The nails of a
dgehog may need trimming. (*See* Rabbits.)

LAND TORTOISES.

Tortoises are popular pets, but although many
kept with great success in Great Britain, the
jority of those that are imported each year are
er looked after adequately, or fail to thrive
other reasons.

Most land tortoises that are imported into Great
tain for sale through dealers are: (1) the
r-thighed Mediterranean Land Tortoise
studo graeca), commonly known as the "Moroc-
tortoise" and sometimes as the "Iberian"
"Algerian"; or (2) Hermann's Tortoise
studo hermanni). The second is distributed in
thern France, Southern Italy, the larger islands
the Western Mediterranean, and parts of
goslavia, Albania, and Greece. There is a
cies found in Greece, the Margined Tortoise
studo marginata), but while adaptable to life
Great Britain, it is more difficult to acquire.
e two common species differ in several ways,
"Moroccan tortoise" having a small bony
r on the back of the thigh. (The upper part
he shell is termed the carapace and the ventral
tion the plastron.)

In selecting a tortoise one should ensure that the animal appears healthy. It should be active and withdraw quickly into its shell on being disturbed. Its legs should be firm and not limp, and there should be no abnormal discharge from the eyes or nostrils. The shell and limbs should be uninjured. Females are generally larger and have a shorter tail than the male. The shield above the tail is flat in the former and curved in the male. It is a good idea to obtain a pair or more of tortoises, but not more than can be looked after with care. On being purchased they should be washed in tepid water.

Many tortoises are given free range in gardens, but this is not advised with all, as they eat a wide variety of vegetables and young plants, and being wandering animals are liable to get lost if the garden is not completely fenced or walled. They should be provided with as large a "pen" or "run" as possible, the walls or wire netting of which should be high enough to prevent their climbing over. The practice of tethering tortoises by a hole in the shell should be discouraged. They should always be provided with a box or shelter, the cheapest form being a wooden soap box turned on one side and with a sufficiently wide entrance, the wood being creosoted and covered with roofing felt. It can be lined with asbestos sheeting if desired, and have its floor covered with dry leaves or other bedding material. Some other shelter should also be provided in the run. The tortoises should be bathed during the hot weather. The occasional application of olive oil will keep the shell polished.

Land tortoises must be fed daily, and it is important to allow them to build up good reserves to enable them to hibernate through the winter successfully. Suitable foods include lettuce, young cabbage, peas, clover, dandelions, and a wide variety of green plants and ripe, sweet fruits. Generally bread and milk should be avoided. For young tortoises especially, it is recommended that once weekly or so the food should be sprinkled with powdered cuttlefish bone, or better still a small quantity of powered calcium gluconate or cod-liver oil. Fresh water in a shallow tray, or even a saucer, should always be provided.

One of the most difficult problems in tortoise keeping is hibernation. Some persons avoid allowing their pets to hibernate by transferring them to a warm place, such as a heated greenhouse; if this is done they must be kept well fed and their place maintained at a summer temperature. It is imperative to do one thing or the other—the half-torpid tortoise that is neither hibernating nor kept at summer temperature will die. Moreover, a tortoise that is allowed to hibernate must not be disturbed.

Signs of pending hibernation, including sluggishness and lowered appetite, are usually evident late in September or early in October. Tortoises living in the garden may commence to bury themselves. If this is allowed they must be well covered, else they may be killed by the ensuing frost. It is, though, more convenient and perhaps provides a greater chance of survival, due to the changeable winter conditions in Britain, to place the animal in a large box, which should be packed with straw, leaves, or hay. The box should be stored in a cool but frostproof place, such as out-building, cellar, or attic. It is important not to create conditions that will awaken the tortoise or tempt it to emerge before the following spring. Rats have been known to attack hibernating tortoises, and so due precautions should be taken.

On emerging from hibernation the eyes and nostrils are somewhat sealed, and should be released by bathing with a 4 per cent. boric acid solution and warm water.

Recently imported female tortoises frequently lay eggs, but it is not a common occurrence for pairs to breed freely in Britain. During the early part of the summer the male is sometimes seen butting the shell of the female, this being a courtship action. If eggs are laid it is unlikely that they will be fertile, and less likely that they can be hatched. They have been hatched by placing them on damp sand and storing them in a warm place—a heated greenhouse or airing cupboard. The eggs should not be disturbed or "turned" once incubation has commenced.

Tortoise ticks are often present on freshly imported specimens, and may best be removed by damping the tick with paraffin or methylated spirits and then removing it gently with tweezers. Round worms are very numerous in tortoises, and should they be seen in the faecal matter the remainder may be eliminated by sprinkling up to one grain of powdered santonin on the food once a week for six weeks. Possibly, some of the newer, safe anthelmintic preparations containing piperazine derivatives may be equally effective. Eye infections are common, and are usually remedied by bathing the eye well with a 4 per cent. boric acid solution or warm cod-liver oil. Continuous discharge from the nose indicates lung infection, and as a primary measure the animal should be kept warm. Bleeding can be stopped by using Friar's Balsam, and care should be taken to prevent insects settling on open wounds.

WATER TORTOISES (TERRAPINS).

In Great Britain the tortoises that have become adapted to life in ponds and rivers are usually termed " terrapins," the name turtle being applied to marine forms. In the U.S.A. and Canada, however, not only the marine species but also terrapins and tortoises are all termed " turtles."

Several kinds of terrapin are available and capable of thriving in Great Britain. These include several American species, the European Pond Tortoise (*Emys orbicularis*), the Spanish Terrapin (*Clemmys leprosa*), the Caspian Terrapin (*Clemmys caspica*), and the Reeves' Terrapin (*Chinemys reevesii*), which hails from China and Japan.

The ideal place in which to keep terrapins is a garden pond within an enclosure. The pond should contain an " island " of dry ground on to which the animals can climb easily. The water should vary in depth, and at one point be at least 2 ft. deep. Provided that there is a suitable " island " the boundary walls of the pond can be upright to prevent escape. The final coat of cement should be smooth and mixed with a waterproofing agent. Shade should be available, not only on the island but also in some parts of the water. This may be provided by suitable plants.

Terrapins are almost entirely carnivorous, although the young of some species may take a little lettuce or other vegetable food. Suitable foods include *small* pieces of raw meat, raw liver (this should certainly be given from time to time), fish, and earthworms. Terrapins prefer to take their food in the water, and it is best to feed them individually if there are several, to ensure that each receives his proper share.

Water tortoises also hibernate. Some bury themselves in mud or sand at the bottom of their ponds, others will dig themselves into the earth in the island or banks of their pond, while others again may go to sleep in the box that, as in the case of land tortoises, should preferably be provided for them on part of ther " land." Should they sleep at the bottom of the pond, it is as well to prevent freezing of the water. One means of doing this is to leave a log or logs floating on the surface. Moving these logs on cold mornings will help to break any ice formed and to prevent total freezing.

AQUARIUM FISH.

There are two types of aquaria—the cold-water, for fish from this and other temperate countries, and the heated, for tropical varieties of fish. Apart from the fact that a suitable heating mechanism—usually electric, with thermostatic control—has to be maintained for tropical aquaria, the general principles governing the two types are much the same. There is a certain amount of additional initial expense in setting up a heated aquarium—the running costs are not high—but in some respects tropical fish are easier to maintain than many of the cold-water varieties.

It should be emphasised at the outset that those who want to keep fish should invest in a proper aquarium and not in a " goldfish bowl," unless the latter be very large in relation to the fish to be kept. Far too many fish suffer from overcrowding or from lack of sufficient water surface. In the case of cold freshwater fish su as carp and goldfish (which need quite differe conditions from tropical fish) it has been calculat that every " 1 in. of body " requires 1 sq. ft. water surface in order to obtain sufficient oxyg for respiration. Thus a fish the body of which (*i.* the length minus the tail fins) is 4 in. will require least 4 sq. ft. of water surface, *i.e.*, an area of 2 ft. 2 ft. Two such fish will require twice this area, a so on. In *The Right Way to Keep Pet Fish* by Dutta (6*s.*), it is pointed out that a goldfish shou normally live for twenty-five years in a suital pond, and grow to its full length of over 14 There are few indoor aquaria capable of supporti many full-grown goldfish in adequate conditio and indeed it is recommended that domes varieties of goldfish such as shubunkins, fantai veiltails, and orandas, which grow more slowly, far better adapted to cold-water aquaria. T pical fish of the varieties kept in aquaria usually much smaller, differ in their oxygen quirements, and can be kept in more crowd conditions. Many have an average body leng of only about 1½ in., and eighteen such fish may maintained in a suitably heated tank with an ar of water surface of 18 in. × 12 in.

A beginner should not only read good books the subject (including *Water Life* publicatio but also consult experts and his local aquarist dealer. Whatever aquarium is chosen, the co ditions should be correct *before* any fish are intr duced. Should fish be suddenly acquired, befo a proper aquarium has been fitted up for the they should be kept in some temporary (b sufficiently capacious) quarters until the aquari is ready.

The instructions for installing and fitting up aquarium are usually supplied, and should followed carefully. The sand that is usua placed on the bottom should be thorough washed, and is best put in a little at a tim Make sure that the inside of the aquarium thoroughly clean before anything at all is p into it. Ornamental rocks may next be intr duced, and great care should be taken to ensu that these are of the correct type, unlikely to ha the fish physically or chemically. Water is th added very gently indeed, and suitable plants s In the case of large tanks the planting is b done when the tank is only partly filled w water, but in any event the plants themsel should be kept wet all the time, or they m quickly shrivel up. In the case of cold-wat aquaria everything may now be left for a f days—preferably a week or more—to ensure th all is well, and to allow certain micro-organis that help form the food of the fish to devel In the case of heated aquaria it is necessary a to ensure that the thermostat is working correct and that the temperature is remaining constant within very narrow limits. Here again it advisable to wait at least a week before int ducing any fish. Should conditions " go wron before or after the fish are introduced, it is best start filling the tank all over again.

Fish should not be overfed, although regu feeding is essential. Attention must be paid the feeding instructions issued with prepa fish foods, and to details given by the supplier " live " foods. Provided fish are neither ov crowded not overfed, the amount of sedime that accumulates in the tank will not be excessi but it should be siphoned away gently eve month, or more often if necessary. Water l by evaporation should be replaced, and in case of heated tanks especially, it is most desira that the added water be of the same temperat as that already in the tanks.

Certain species of water snail are often pla in aquaria to act as scavengers. It is necess to ensure that, if snails are kept, they are of right type, and it is important to consult expe on this matter.

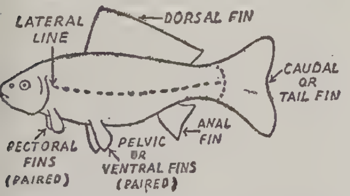
Breeding is an interesting topic, there be both egg-laying and viviparous or " live-bearin fish. The beginner is well advised to learn f how to keep fish in healthy condition in aquarium before indulging in any planned bre ing, and he should study the relevant informat in books on the subject.

An aeration plant is often recommended on grounds that it will increase the fish-carry acity of the aquarium. This is true up to a t, but overcrowding may bring other troubles des those connected with lack of sufficient gen, and the golden rule is never to keep too y fish for the size of aquarium in question. ther factor to be remembered is that should aerator break down it may leave the fish with oxygen than their proper requirement. It been recommended that an aerator is best ght of as a stand-by, to be employed only in rgencies, *e.g.*, when for some reason extra have to be added to a tank already holding or almost all its proper capacity.

here are unfortunately many diseases of fish, as yet scientific knowledge concerning many nem is far less detailed than it should be. It is r, however, that environmental factors are onsible for many deaths or cases of unthrifti- , and among the factors concerned may be d: overcrowding, overfeeding, the provision diet that is qualitatively inadequate, lack of lance " in the aquarium leading to unsuitable litions, dirt, too strong light, lead paint and ious substances, that may somehow have e into contact with the water (*e.g.*, from the ds of the person tending them) or been abed from the atmosphere. One must be careful uch things as disinfectants, soaps, petrol, etc. he case of tropical fish the temperature of the er may be incorrect. Should fish troubles r, therefore, it is as well to consider these ous possibilities, although one should not tate to seek professional advice where there ears to be a case of infectious disease. An ail- fish should certainly be removed from the (assuming that there are other fish present) given separate quarters of its own if such a se is feasible.

is not intended to provide a description of the rate diseases, although it may be mentioned such signs as the appearance of material mbling cotton-wool (actual fungal growths) "rotting" of the tail or fins, are among those should lead the owner to isolate affected fish to seek help immediately.

o attempt is made here to describe any of the y different species and varieties of fish suit- for private aquaria. Some of the "points" fish are shown in the accompanying illustra- . Great care must be taken in mixing ies, *e.g.*, "hard mouthed" and "soft thed" kinds should not be kept together. temptation to put other species (*e.g.*, newts) aquarium fish must likewise be avoided.

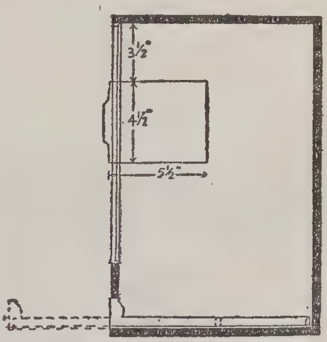


CAGE BIRDS.

ery many species and varieties of birds are maintained successfully in captivity, and e exists in Great Britain a large and expand- "cage-bird fancy," that caters for a consider- proportion of the smaller birds adapted to or aviary life. The increase in the numbers udgerigars since the end of the Second World has been phenomenal, and it was estimated ng 1957 that the numbers of the species alone he United Kingdom exceeded 6 millions, the esponding figure for the U.S.A.—where the ular name is "parakeets"—being over nillions.

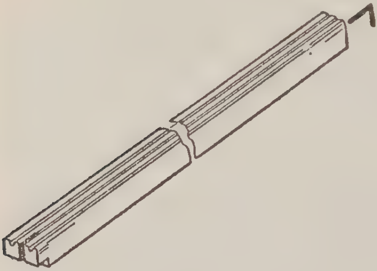
he different types and sizes of birds have rent requirements, and in the space available not possible to do more than cover the general ciples and to deal briefly with the special acteristics of the management of the more y maintained species. The beginner is ad- l to restrict his attention to one of the better-known species, *e.g.*, canaries or budgerigars, and not to attempt to maintain exotic varieties until he has acquired considerable experience.

Most species thrive best in aviaries, which may be indoor, outdoor, or of the combined "outdoor–indoor" type. An indoor aviary is usually all-wire and portable. The criticism of many such aviaries is that they tend to be high and narrow, whereas a fairly large floor-space is desirable. They should not be placed in cold or draughty places, nor too near a fire. If sited so as to receive much direct sunlight they must have adequate shelter. The wires must be close together, especially if smaller species are kept, a distance between them of about ⅜ in. being generally suitable. An outdoor aviary—suitable only for some species or at certain times in the case of others—should occupy a sunny position, although it too must include shade, and must be protected from winds. There ought in fact to be a sheltered portion, dry and well protected from the elements. The aviary must be strongly made and safe from all predators, including rats and mice. While it is often considered desirable to allow herbage to protrude through the wire-mesh floor, it is essential that the birds are never in close contact with wild rodents or their droppings. Most birds are highly susceptible to some forms of *salmonellosis* (see under mice and guinea-pigs), and can contract them in this way. It is advisable also that the roof of the aviary is solid: corrugated asbestos sheeting, projecting well clear of the edges of the uprights so as to prevent water and other matter from entering the interior, is excellent. The droppings of wild birds may be a potent source of bacterial infection or of internal parasites. To prevent close contact otherwise with wild birds, the wire or wire-netting "walls" of the aviary may be double. If an "outdoor–indoor" aviary is employed, there is usually an indoor flight cage, separated from the external portion either by a very light hanging door of suitable size, through which the birds can easily push their way, or by a sliding partition that the owner can operate as required.

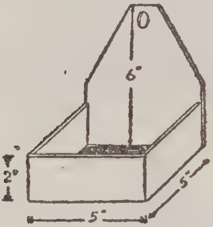


Section through Cage.

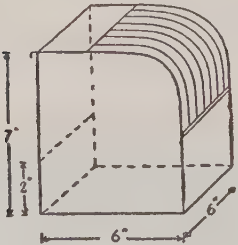
If an aviary is out of the question, then a suitable cage should be purchased or constructed. The cage need not be ornate—indeed simplicity of design usually facilitates the highly important task of keeping everything clean—but it must be large enough. A cross-section through a breeding-cage suitable for canaries, and for many other species, is shown in the accompanying illustration. Such a cage should measure about 40 in. in length × 12 in. wide × 18 in. high. It is constructed of wood or some suitable sheeting except for the front, which consists of vertical wires with horizontal stays, and can be divided into two parts by means of a suitable partition containing a removable section made of wire. By this means the cock and hen canaries can be introduced into the separate sections and develop a courtship before being allowed to be together for actual mating. The cross-section indicates the site and size of the removable portion of the partition, and it shows also the removable tray that is such an excellent fitting for almost any type of cage, and which greatly facilitates cleaning.



PERCH.



NESTING-BOX WITH PLAIN WOOD BOTTOM.

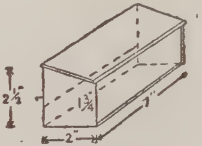


BIRD BATH.

Whether an aviary or a cage is employed, it is essential to have proper fittings, including conveniently placed drinking-troughs, feeding-trays and bird-baths, and good perches. Much unnecessary discomfort is brought about through the use of unsuitable perches, or ones that are incorrectly situated or not sufficiently "firm." A suitable type of perch, of which there should be several in the cage or aviary, is shown in the accompanying illustration, and it should be of the appropriate dimensions for the size of bird. In the case of the larger canaries (Norwich and Yorkshire), *e.g.*, the sectional measurements should be ⅝ in. × ¾ in., whereas for a smaller canary (Border) they should be ½ in. × ⅝ in. The type of perch shown is easy to clean and does not possess awkward corners in which parasites may be harboured. The dimensions of a nesting box a bird-bath, and a feeding-tray suitable for canaries are also given in the accompanyi illustrations.

While wood is a convenient material for avia and cage construction, it has, of course, seve disadvantages. Out of doors it is best creosot (lead paint must never be used for places which birds or other small animals are kept), a indoors it is better lined with hard asbestos she ing. Metal is suitable—provided that it does r rust or corrode and that the environmen conditions are warm enough.

In all cases a supply of clean, fresh water shou be available. Strict cleanliness should be c served, and professional advice taken immediat if a bird is not thriving.



SEED TROUGH.

CANARIES (*Serinus canarius*).—These domesticated forms of the race of wild serin fou in the Canary Islands, and may live up to twen five years. Many varieties are known, a although most individuals are "canary yellov other colours have been developed by fancie Many books have been written about the cana although there is still much to be learned conce ing its feeding and diseases—as is indeed the c with almost all cage-birds. The system of fe ing generally recommended is based upon mixture of 2 or 3 parts of canary seed (which rich in energy, and which is sometimes mi with a little millet seed) to 1 part of summer ra seed, which is high in fat and protein. Th seems to have been some difficulty in obtain suitable rape seed in some areas since the w The best is German summer rape or Rübsen ra Other seeds are employed as substitutes, or special purposes, *e.g.*, niger is usually added breeding time, and linseed if there is any indi tion of premature or soft (out-of-season) mo Good proprietary seed mixtures are availal A little greenfood should be provided tw weekly, and a piece of cuttlefish bone pla between the wires is a suitable source of calciu Soft-bill food (containing boiled egg, dried yolk, dried flies, and ants' pupæ) is also reco mended by many breeders, while others g chopped egg alone. Others again favour m especially for young birds.

Breeding is usually started late in March or ea in April, but not unless the daily shade tempe ture is at least 50° F. The pairs should selected earlier than this and transferred breeding-cages, with the partition in positi By the middle of February the wire partit may be installed so that the two birds can one another. A little niger seed is usually ad to the diet, while finely ground oystershell eggshell may be sprinkled on the floor. (Otherv the floor may be covered with washed sand tha not too fine and is free from dust.) When birds begin to feed one another through the v they are ready for mating, and the partition n be removed. The nest-box can then be inser and suitable nesting materials, *e.g.*, cow hair moss, placed in the cage. The incubation pe is thirteen to fourteen days. After the eggs laid some owners prefer to separate the cock the hen, but allow him to rejoin her after young are all about eight to nine days old have opened their eyes. If it is desired that the chicks be hatched together, then one remove the first three eggs that are laid—usu one egg is laid daily—and keep them in a box room temperature, substituting dummy eggs them in the nest-box. On the afternoon of third day of laying they are returned to the n box in place of the dummies.

/hen the young chicks are able to feed for them-
es they should be provided with special food,
n as egg and bread crumbs and a little cracked
ary seed. If the cock bird interferes with them,
auses the hen to neglect them, he must be re-
ned to his own section. Usually, however, all
s well, and the hen will go to the nest again
n the first chicks are almost sixteen days old.
ne three or four broods may be raised in a
on.

/AXBILLS, FINCHES, AND OTHER SEED-
TERS.—The canary is of course a finch, but
t of the other " foreign finches " are considered
dealers and writers together with other types
seed-eating birds. Well over 30 species of
davats, *Buntings*, *Mannikins*, *Cardinals*, *Why-*
s, *Weavers*, and *Finches* of various descriptions
e been maintained successfully in capitivity in
at Britain. One of the most popular is the
ra finch (*Taeniopygia castanotis*), from Austra-
which has bred so successfully in this country
supplies no longer depend upon fresh impor-
ons, and which is already appearing in several
eties. The native bird, and many of its
endants, are grey and white, with red beaks.
male bird has orange cheek-patches, and
nge flanks with white markings. The throat
black barring on a white background, and
ed the characteristic markings of the male
e been the subject of interesting behaviour
lies. The female lacks these special markings.
species is hardy, and is capable of living in
loor aviaries all the year round, so long as it
shelter from draughts or strong winds and
quate facilities for roosting. If provided with
-boxes, the birds will attempt—often success-
—to breed all the year round, so to avoid
rbreeding it is better to remove these boxes in
ter. A mixture of millet and canary seed
ns the basis of their diet, which should be
plemented with fresh greenfood, millet sprays,
grit, and cuttlebone—and, of course, fresh
er should be available. Another bird suitable
the relatively uninitiated bird-keeper is the
galese (a domestic variety of *Munia striata*).
eems that these birds are the result of careful
ding by the Japanese, and may be regarded
fertile hybrids. Three main forms, the
colate-and-White, the Fawn-and-White, and
White, have been developed. These birds
thrive in cages or in aviaries. As in the case
ebra Finches, they will attempt to breed all
year round if provided with nest-boxes.
galese are sociable birds, sometimes known
he U.S.A. as Society Finches. They appear
equire less additional food than most species,
ving on a mixture of canary and millet seed,
ether with grit, cuttlebone, and an occasional
et spray or item of greenstuff.
or details of these birds, and of the many
ers from which a selection may be made, works
reference should be consulted. Three very
ul books, all published by Cage Birds, London,
Foreign Bird Keeping, by Edward J. Boosey
.), *Foreign Birds for Beginners*, by D. H. S.
ion (10*s*. 6*d*.), and *Foreign Birds for Garden*
ries, by Alec Brooksbank (10*s*. 6*d*.).

UDGERIGARS.—The increase in the popu-
y of this bird has been phenomenal, although to
e who have experience of other birds as pets the
ons are soon fairly obvious. Apart from the
city to talk, shown by many birds—especially
es—kept alone and trained, there is a liveliness,
ost a " cheekiness," and an apparent like of
an companionship. The wild green budgeri-
(*Melopsittacus undulatus*) exists in large
bers in the grassland and desert shrub regions
ustralia. The usual colour is grass green—it
equently known as the Grass Parakeet—with
llow mask, with three black spots on either
As a result of intensive breeding, a con-
able number of colour varieties has been
uced, and the genetics of colour are a constant
ce of interest to budgerigar breeders. A vast
erigar " fancy " has been built up in the
ed Kingdom, the U.S.A., and other countries,
World Budgerigar Congresses are held every
years. Budgerigars will thrive in outdoor
ries all the year round, but the vast majority are kept as indoor pets in cages or small aviaries. The cages can be similar to those used for canaries, and care should be taken that the perches are of the correct diameter. If nest-boxes are put up, and the environmental conditions are suitable, budgerigars suitably paired will breed at almost any time of the year. It is customary, however, to restrict breeding to the spring, summer, and early autumn. Overbreeding may lead to difficulties, including the production of " runners " or " French moult." The sexes may normally be distinguished, at any rate in mature individuals, by the colour of the cere at the base of the beak, which is blue in males and brown in females. Males may lose their colour if not in good condition and for other reasons.

There are now many proprietary seeds mixtures, but some owners prefer to make up their own mixtures of millet (usually mixing small yellow and large white varieties) and canary seed. Millet sprays, fresh greenfood, good grit, and cuttlebone are all desirable, and it is important that the correct size and consistency of grit be chosen. Variety in " extras " to the basal seeds diet is probably important, for the captive bird has not the same opportunities as its wild ancestors for ranging widely for, possibly, important trace items of food. Breeding birds secrete a " milk," comparable with the crop milk of pigeons and some other birds, and this is of importance in the early feeding of the young.

Most healthy budgerigars seem to live to the age of 5–7 years or more, and considerably greater ages have been attained in captivity.

Such is the development of the budgerigar fancy that most equipment as well as food can be obtained ready for use. The playful habits of budgerigars have led to their being given table-tennis balls or a variety of small toys to play with, while some forms of food are supplied as budgerigar bells or otherwise in special shapes that seem to amuse the birds as they take the constituent seed from them.

The study of budgerigar diseases is in its infancy, but already some important facts have become realised. *French moult* is certainly reproducible by overbreeding, and may be linked with deficiencies in the ability of the parent birds to feed their young—or to hand over to them at the time of laying sufficient nutritional reserves to carry them through hatching and parental feeding until the time that they can fend for themselves. A deficiency in the " milk " has been shown in some cases, and may be generally true. Large chicks can be produced by killing off or removing all but a single member of the clutch, and allowing the parents to deal with it alone.

A mite infestation, due to *Cnemidocoptes pilae*, may give rise to *Scaly face*, *Scaly beak*, or *Scaly leg*, for which veterinary treatment is now available. Another condition, known as *Brown hypertrophy of the cere*, is characterised by thickening and darkening of the surface of the cere. In the early stages it is sometimes thought that the bird is changing its sex. There is no known successful treatment at the time of writing, and if the overgrowth is cut away it will only reform. There are various disturbances of the *digestive tract*, and some of these may be associated with inability to stand properly.

There are many treatises on the budgerigar. A useful little work is *Budgerigar Guide*, by Cessa Feyerbrand (Fond du Lac, Wisconsin: All-Pets Magazine).

LOVEBIRDS AND PARROTLETS are also members of the parrot family, and while they are unlikely to equal the budgerigar in popularity, they are nevertheless interesting birds that are being kept in increasing numbers as pets. Lovebirds, of the genus *Agapornis*, are African in origin, and some six species are commonly kept in captivity. Parrotlets derive from South America, the commonest species being the Guiana Parrotlet, *Forpus passerinus*. Both types of bird are relatively simple to maintain in aviaries or large cages, and their basal diet (which should be supplemented widely) is a mixture of millet and canary seed. They are hardy and vigorous creatures, many details of which are to be found in condensed form in *Lovebirds and Parrotlets*, by C. P. Luke (London: Cage Birds, 8*s*. 6*d*.).
